The fat-embolism suggests that the pulmonary circulation was maintained for a finite time after the cranial or thoracic fractures were sustained. In 5 of these bodies all the vessels forming the vascular peduncle of the heart (including the pulmonary arteries) were either extensively torn or completely severed. We therefore suggest that these injuries to the great vessels occurred a sufficient time after the fractures for pulmonary fat-embolism to develop, and that during this time the intrapulmonary vascular bed was also largely intact.

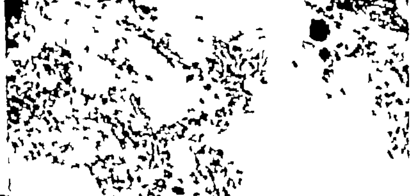

Fig. 4—Naples accident: body C. Pulmonary fat-embolism. (Sudan III and IV. ×200.)

PATHOGENESIS

Lung injuries of a similar type have been described before, clinically or under experimental conditions, in at least three different situations: (1) in exposure to the effects of explosive blast; (2) as a result of very rapid ("explosive") decompression; and (3) as a result of certain severe forms of body impact and abrupt deceleration. Initially it seemed reasonable to suppose that any or all of these conditions might have prevailed at some time during the course of events associated with sudden structural failure at high altitude of a pressurised aircraft such as the Comet. It was therefore necessary to investigate each of these possibilities in some detail.

Blast Injury

The pathological and physiological effects of air blast from gunfire or detonation of high explosive have been observed in animals under experimental conditions (Hooker 1924, Zuckerman 1940, 1941).

Rabbits, mice, and other species killed outright showed no external injuries, but nearly all had blood or blood-stained froth in the upper respiratory passages. The outstanding lesions in all specimens killed or injured were alveolar disruption and massive pulmonary hæmorrhage, amounting in places to complete hepatisation. The injurious effects of blast diminished with increasing distance of the animals from the explosion. Hæmorrhages under the visceral pleura tended to assume a linear pattern of distribution, forming the so-called "rib markings." Animals exposed to underwater blast developed essentially the same pulmonary pathology (Williams 1942, Cameron et al. 1942). More recently Greaves et al. (1943) and Clemedson and Granström (1950) have shown that the subpleural hæmorrhagic bands do not correspond to the ribs but lie beneath the intercostal spaces.

Cases of death or injury in man due to air blast have been reported (Hadfield et al. 1940, O'Reilly and Gloyne 1941, Osborn 1941, Wilson and Tunbridge 1943). Lung damage, termed "pulmonary concussion," was similar to that described by Zuckerman (1940). Hæmorrhagic "rib markings" were the rule in children, just as in the experiments on animals, but in many adults such markings were not found. Elasticity of the chest wall may be a determining factor in this matter. Nearly all the fatalities and most of those severely injured had blood or bloodstained froth issuing from nose and mouth. In actual bomb incidents, however, severe pulmonary concussion was usually accompanied by additional evidence of the explosion, such as skin wounds caused by flying missiles (including bomb fragments) or burns from the fireball.

Very little is known for certain about the precise mechanism of pulmonary concussion, beyond the fact that it is an impact phenomenon resulting from impingement of the positive pressure component of the blast wave on the body wall (Zuckerman 1940). Three ætiological factors have been suggested: (1) direct deformation of the lung tissues (Osborn 1941); (2) differential acceleration of the various structural elements of the thorax (Clemedson and Granström 1950); and (3) transmission of a shock wave through the tissues (Williams 1942). It may not be a question of which theory is correct, but how much each factor contributes in any particular instance. Presumably the same factors operate whenever this type of lung injury, localised or diffuse, results from any form of non-penetrating blow to the chest wall. Penney and Bickley (1943), analysing unpublished numerical data on blast injury provided by Zuckerman, proposed that the lungs of any animal, including man, severely injured if the chest walls are flung inw

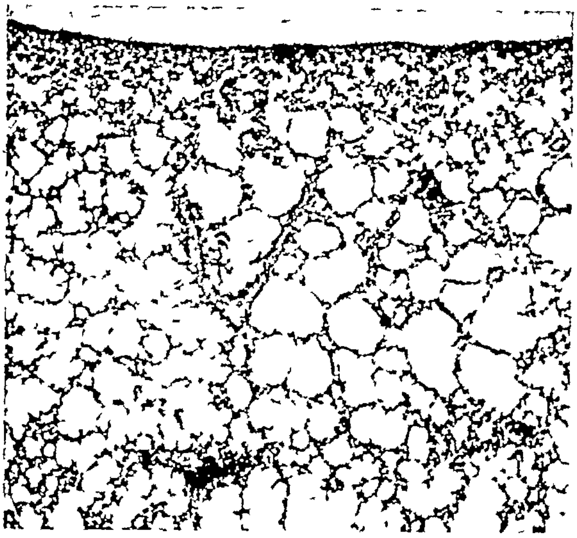

Fig 5—Guineapig lung after explosive decompression from 0 to 35,000 ft. in 0 006 sec. (Hæmatoxylin and eosin ×40)

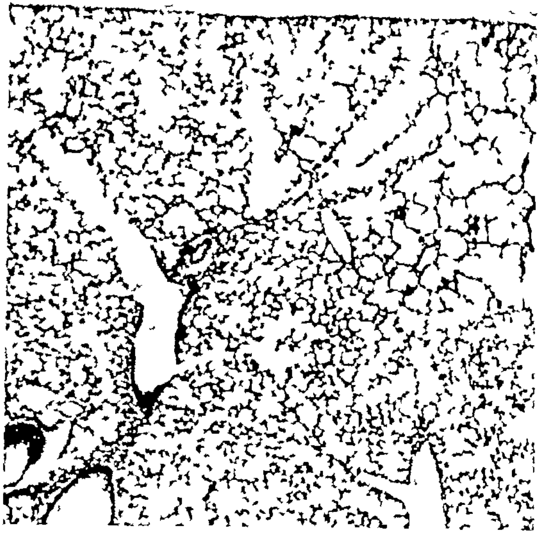

Fig 6—Lung showing normal appearance in control guineapig killed with ether (Hæmatoxylin and eosin ×40)

such acceleration that they acquire a velocity of 20 metres per sec in half a millisecond or less

Analysis of the necropsy findings in the Comet victims has led us to conclude that the pulmonary lesions were in all probability not caused by an explosion, the reasons being as follows

(1) In none of the bodies recovered (including that of a child aged 10 years) did the subpleural hæmorrhages show a pattern of "rib markings"

(2) The lungs of all had much the same appearance, whereas in blast a significant variation in the degree of injury might be expected, people seated near the source being most severely affected

(3) In no case was blood or froth present in the nose, mouth, or elsewhere in the upper respiratory passages

(4) None of the bodies had skin lesions attributable to peppering with metallic fragments or other missiles

(5) None had burns such as are caused by naked flame

Incidentally, it may be noted that examination of the wreckage recovered from the sea bed off Elba led structural experts to conclude that there was no evidence of a bomb explosion or of any fire inside the cabin of the aircraft

Explosive Decompression

The possible dangers of failure of a pressurised cabin at high altitude have been studied by physiologists since they were first consulted by aircraft designers about 20 years ago, when commercial high-altitude flight was first advocated Initial fears were soon allayed by experiments (Heim 1938, Garsaux et al 1939, Bergeret and Giordan 1939) Military applications of high altitude flight led to an intensification of research, and experiments made on man in this country (Flying Personnel Research Committee 1942), the United States (Sweeney 1944, Hitchcock 1953), and in Germany (Benzinger 1950) showed that man can tolerate extremely rapid decompression without ill effect After the war, when civil pressurised transport aircraft became a practical proposition, there was an urgent need for a clear exposition of the limits of human tolerance, so that an aircraft designer could estimate the risk to passengers from failure of a given area (e g , a door, a window, or a hatch) at a known pressure differential A formula, based on an interpretation of some experimental data, was proposed by Lovelace and Gagge (1946) Its validity has recently been challenged (Fryer 1953, Violette 1954) and an alternative means of assessment devised (Violette 1954)

O[illegible] ledge of the pathological sequelæ of explosive d[illegible] is based upon two sets of data (1) the results of very numerous experiments on animals (Eggleton et al 1945, Hitchcock 1953, Rotondo 1953), and (2) a little information on the injurious effects of explosive decompression on man In animals it has proved very difficult to cause death or even symptoms, provided that prolonged anoxia has been avoided For example, of 19 dogs decompressed from 10,000 to 50,000 ft (a pressure differential of 8 4 lb per sq inch) in 0 012 sec none developed any symptoms, although small areas of pulmonary hæmorrhage could be detected if the animals were sacrificed soon after the experiment (Edelmann et al 1946) Of the lesions described by various workers, the most predominant has been scattered pulmonary hæmorrhages, often accompanied by areas of collapse Emphysema has also been described, and "rib markings" were noted by Rotondo (1953) In none of these experiments was the injury comparable in severity with that found in the Comet victims, and some of it at least can be attributed to the methods of sacrifice used after recompression Cole et al (1953) report more extensive lesions, but in these experiments the picture was undoubtedly complicated by exposure to atmospheric pressures below that of the vapour pressure of water at body temperature—i e , when the tissue fluids "boil" The lung damage in these circumstances exceeded anything previously observed in experimental explosive decompression

In experiments at Farnborough 10 adult guineapigs were decompressed from 0 to 35,000 ft (11 2 lb per sq inch) in 0 006 sec and then immediately brought to ground level The guineapigs appeared mildly startled by the experience but showed no signs of respiratory distress and behaved quite normally during and after recompression They were then killed with ether Outwardly the lungs appeared congested in most specimens, but in 1 there were distinct hæmorrhagic "rib markings" Microscopically there was congestive atelectasis interspersed with areas of alveolar distension (fig 5), but rupture of alveoli was uncommon, and hæmorrhages were few and widely scattered

The lung lesions found in animals may be explained (at least in part) by the development of high pressure differences between the lungs and the atmosphere, with resulting overdistension of the thorax if the rate of environmental decompression is greater than the maximal rate at which the lungs can void their contents through the trachea

The ill effects noted in man are few Two cases of pneumomediastinum (Vavala 1954) and 1 of death from rupture of the lungs and massive air embolism (Benson

1953) have occurred in the course of many hundreds of explosive decompressions under identical conditions during routine altitude tests in the United States Benzinger described two incidents in Germany in which air-embolism is thought to have occurred during voluntary breath holding in the course of explosive decompression. These phenomena are known complications of the decompression incurred during submarine escape if the glottis is closed (Polak and Adams 1932) Pneumomediastinum may similarly result from pulmonary alveolar rupture allowing air to track interstitially via the hilum to the mediastinal tissues It therefore appears that closure of the glottis might render serious or fatal an otherwise harmless decompression No pulmonary lesions resembling those found in the animals have ever been observed in man after explosive decompression

It is seen, then that the widespread pulmonary lesions of the Comet victims might be attributable to explosive decompression if the conditions were such that the violence of the decompression exceeded the limits of human tolerance by a wide margin On the basis of the formulæ derived by Lovelace and Gagge (1946) the possible borderline between safety and "uncertainty" would correspond in the case of the Comet flying at 30 000 ft to the instantaneous breaching of the cabin wall by removal of an area of 154 sq ft In such circumstances the decompression would take 0 062 sec However, the more recent interpretation by Violette (1954) suggests that injury would result only if an area of more than 290 sq ft was lost, giving a decompression time of 0 032 sec In fact the expert examination of the wreckage of the Comet aircraft G ALYP suggests most strongly that the primary failure involved the loss of a maximal area of 162 sq ft, and that the splitting process which resulted in this failure took a finite time, which prolonged the decompression well beyond the calculated 0 059 sec in the case of instantaneous disruption In Sweeney s experiments decompression from 8000 to 35 000 ft (7 5 lb per sq inch) in 0 09 sec proved completely innocuous for 15 young adults and 160 decompressions from 10 200 to 35 000 ft (6 55 lb per sq inch) in 0 075 sec caused no ill effects

From such considerations it seems most unlikely that all the occupants of the aircraft should have sustained severe pulmonary injury from the primary effects of explosive decompression in the circumstances suggested by investigation of the wreckage In addition it is noteworthy that there was no evidence in either accident of gross air-embolism or of mediastinal emphysema

A second and probably more relevant result of explosive decompression is the expulsive effect of the air released when a large pressure-cabin fails This is discussed more fully below

Impact

Fatal falls from a great height to the ground are not uncommon it is well known that in such cases there may be extensive internal injuries even when there are few external signs of trauma (Gosselin 1847 Moritz 1954) The destructive *forces involved are presumably much* the same as when the body is struck by a blunt moving object or by a blast wave the only difference appears to be that here the effects are decelerative rather than accelerative An important contribution on this subject was made by American workers investigating the rôle of deceleration in the genesis of injuries in military aircraft accidents Hass (1944) referred to 21 cases in which at necropsy laceration hæmorrhage and traumatic emphysema in the lungs were found there was also tearing of the heart and aorta laceration of the liver spleen and ileum and much free blood in the body cavities Similar lesions were produced experimentally in animals by very abrupt deceleration (Rushmer et al 1946 Rushmer and Hass 1940) The injuries were attributed partly to direct deformation and partly to differential deceleration of the tissues To these should be added the possibility of shock wave propagation

Since the Comet G ALYP is known to have broken up at high altitude there is reason to suppose that the occupants of this machine were twice subjected to decelerative forces; inside the aircraft at the time of initial failure and on impact with the sea The altitude at which they left the fuselage is a matter for speculation, but a free fall of 2000 ft is adequate for a human body to attain its terminal velocity of about 160 ft per sec It is important to know whether the internal injuries could have been caused partly or entirely by impact with the sea The observations of Merkel (1926) and Ziemke (1928) on falls into water from heights of up to 150 ft suggest that this is most probable and that death may take place without signs of drowning Very little is known about these matters, and it has been necessary to investigate them experimentally in guineapigs

EXPERIMENTS ON GUINEAPIGS

Rationale of Experiments

The forces generated by impact of a rigid sphere with a water surface were studied by Richardson (1948) and from his results it has been possible to deduce the approximate incident velocity necessary in any given species to produce the inward movement of the chest wall specified by Penney and Bickley (1943) as critical for the production of blast injury in the lungs Details of the mathematical method have been published separately (Stewart et al 1955) and the calculations showed that the critical incident velocity for the mouse would be about 118 ft. per sec for the guineapig 90 ft per sec and for man 94 ft per sec

Material and Methods

A vertical catapult was constructed for projecting anæsthetised or dead guineapigs at known velocity into a tank of water 5 ft deep The catapult consisted of a small metal carrier moving vertically on a tubular steel upright and powered by six strong rubber cords The carrier could be raised to the desired height with a block and tackle and was fired by a manually operated release The guineapig was lightly secured by strips of adhesive paper to the under surface of the carrier so that when the latter was arrested at the lower limit of its excursion the guineapig was projected belly first about $2^1/_2$ ft through the air before hitting the water The attitude on impact was checked by cinephotography which revealed that the body usually rotated a little in the air The incident velocity was measured in two ways by high speed cinephotography and by an electrical method using a slide wire connected to the carrier These gave almost identical results

The guineapigs were either male or female albinos weighing 300–400 g 10 guineapigs were projected into the water at velocities between 66 and 117 ft per sec 6 were anæsthetised with ether and the 4 others received an overdose of ether so that all respiratory movements had ceased 10 minutes before the experiment Preliminary experiments showed that many anæsthetics and commonly used methods of killing animals in the laboratory may by themselves cause a remarkable degree of hæmorrhage or vascular congestion in guineapig lungs Coal gas was particularly injurious sometimes even producing rib markings Several control specimens killed with ether however, showed no evidence of pulmonary damage on naked-eye and microscopical examination (fig 6)

In 3 of the anæsthetised guineapigs subcutaneous electrocardiographic electrodes were inserted into the right forelimb and both hindlimbs before they were fixed to the carrier After the catapult was fired each animal was left in the water for one to two minutes Anteroposterior and lateral radiographs of the whole body were taken and the guineapig was then dissected Particular attention was paid to the condition of the thoracic and

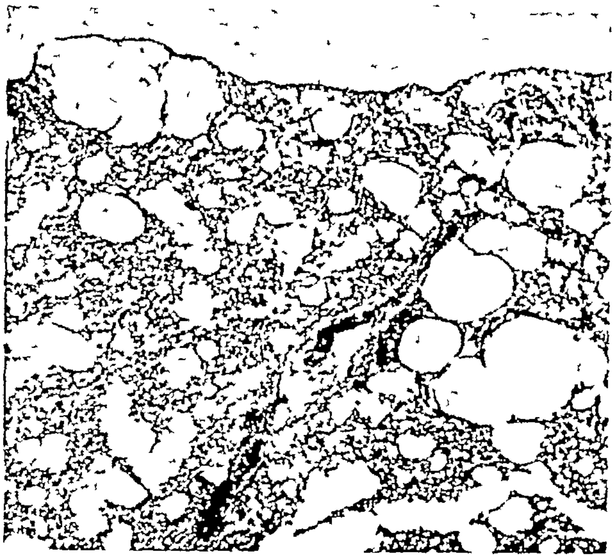

Fig 7—Lung from anæsthetised guineapig projected into water at 117 ft. per sec., showing intrapulmonary hæmorrhage and traumatic emphysema. Compare with figs. 1 and 2 (Hæmatoxylin and eosin × 40)

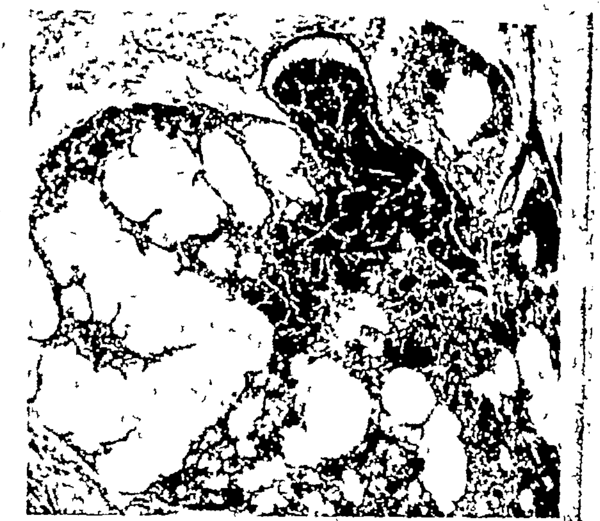

Fig 8—Lung from an anæsthetised guineapig projected into water at 107 ft. per sec. Note large bronchial plug composed mainly of stripped epithelium (Hæmatoxylin and eosin × 68)

abdominal contents The trachea was first ligated, the chest was opened, and the heart and lungs were examined in situ. In some guineapigs these organs were removed, photographed, and fixed by submersion in Zenker-formalin In others the hilum of the right lung was ligated, the left atrium opened, and the left lung then perfused through the pulmonary artery, at a pressure of 20 mm Hg, with physiological saline solution followed by Zenker-formalin at 37°C, next, the thoracic contents were removed in toto and fixed by submersion in Zenker-formalin for a further twenty-four hours In every case paraffin sections were prepared from each lobe of both lungs, and stained by the same techniques as used for the human necropsy material

1 other guineapig was projected at a velocity of 100 ft per sec into a large pile of cotton-wool instead of into water, this was done as a control test to determine what effects, if any, might be attributable to the acceleration of the catapult

Results

On recovery from the water all the guineapigs showed little external sign of injury, but all of the anæsthetised guineapigs were now dead Most had some body flattening, 4 had bruises on the inner sides of the limbs or under the mandible, 1 had lost most of the hair from a large area on the front of the thorax, and 4 had palpable fractures of the right tibia

Internal injuries were severe The lungs of all 4 guineapigs projected into water at velocities of 104 ft per sec or more were extensively damaged, much as in cases of severe blast injury Subpleural hæmorrhages were found on all surfaces of both lungs, in many areas they were confluent and in places (particularly on the posterior surfaces) they formed a distinct pattern of " rib markings " There were patches of subpleural emphysema and occasional small tears on the costal and diaphragmatic surfaces Microscopically there was generalised pulmonary disruption with massive hæmorrhage (fig 7), the traumatic emphysema amounted in places to cavitation Intervening small areas of collapsed or of relatively normal lung tissue were present Many bronchi were partially or completely occluded by plugs consisting of material staining with periodic acid Schiff reagent and sh[illegible]f bronchial epithelium which seemed to have [illegible]ped from the bronchial wall with disruption of [illegible]vidual cells, occasionally it appeared as if the [illegible]onchial epithelium had moved distally, blocking alveolar ducts and even alveoli (fig 8) Some large pulmonary blood vessels and lymphatics were torn across, whereas others were abnormally congested In all the guineapigs the upper lobes tended to be less severely affected than the middle and lower lobes

Similar but localised pulmonary lesions were found in guineapigs projected into the water at velocities of 75–101 ft per sec Two guineapigs projected at 66 and 73 ft per sec showed only patchy subpleural ecchymoses and congestion of the pulmonary vessels The control guineapig projected into cotton-wool developed a single subpleural ecchymosis on the anterior margin of the left upper lobe The lungs were also congested but otherwise intact, and the only other lesion found was a small hæmorrhage into the perinephric fat

Throughout these experiments no difference in lung pathology could be seen between the anæsthetised and dead guineapigs, in none of the former was there any evidence of death by drowning

Necropsy findings other than in the lungs can be summarised briefly Most of the guineapigs had a few small hæmorrhages into the muscles of the chest wall Hæmothorax was present in 6 cases, hæmopericardium in 3 Cardiac distension, particularly of the right ventricle was obvious in 4 guineapigs, and in 2 there was a small tear in the wall of the right atrium close to the point of entry of the inferior vena cava In the abdomen there was free blood in the peritoneal cavity in 10 guineapigs, ruptures of the stomach or intestinal tract in 7, lacerations of the liver in 7, a splenic tear in 1, and multiple mesenteric or retroperitoneal hæmorrhages in 7 The diaphragm remained intact Skeletal injuries seen in the radiograph were not extensive, they were a constant finding only in guineapigs projected into water at the highest velocities Minor fractures of the skull were found only twice, spinal fracture dislocations appeared in 3 cases, costovertebral dislocations in 2, and various limb fractures in 5

Owing to technical difficulties a continuous electrocardiographic record was obtained in only 1 guineapig abnormal cardiac activity being recorded after impact with the water at a velocity of 95 ft per sec There was complete atrioventricular dissociation, but ventricular activity persisted for some minutes in an altered but regular form, evidently controlled from a ventricular ectopic focus

Conclusions

(1) The experiments suggest that severe internal injuries may be expected as a result of impact with a

water surface The pulmonary and intra abdominal lesions are essentially the same as those found in the Comet victims The latter did not have "rib markings" but this is probably acceptable as a species difference Such markings are readily produced in guineapigs not only by blast and impact but also by explosive decompression and even coal gas poisoning whereas in man many cases of severe lung damage from air blast and from body impact have not shown this phenomenon Nor is it a feature of coal gas poisoning in man

(2) The degree of lung injury from water impact is related to the incident velocity the critical velocity for generalised injury in the guineapig being about 104 ft per sec This is close to the predicted value but owing to the approximate nature of the calculations this must be regarded as largely fortuitous

(3) Living anæsthetised guineapigs may be killed by the impact and show no evidence of death by drowning

Skin Lesions

ELBA ACCIDENT

In 14 of the 15 bodies recovered from the sea at Elba there was a similar type of skin damage The affected areas had the following features

(1) They were red and their peripheral margins were distinct but irregular in outline

(2) In some bodies they were traversed by parallel-sided bands of apparently undamaged skin

(3) In most cases the affected parts were beneath the clothing found on the cadaver when removed from the sea.

(4) There was no evidence of scorching or singeing of hair or epidermis but in places there was some exfoliation.

(5) None of the clothing was burnt or decomposed in any way

(6) Some of the areas of skin damage corresponded closely to yellowish stains on the adjacent and overlying garments.

13 bodies showed this type of injury on the back and/or buttocks 3 of these bore further lesions: one on the calf a second on the thigh and temple and the third on a small area under the chin Of the remaining 2 bodies 1 that of a corpulent adult male had a large area of altered skin on the front of the trunk only and the last body was completely unmarked in this respect

Histologically these lesions showed no signs of vital reaction The epidermis was in some areas intact in others separating or absent Epidermal cells usually showed a vacuolar change An accumulation of brown pigment like granular material in the basal cells and occasionally in malpighian and horny layers was noted in 4 of the 5 specimens from pale-skinned European bodies The dermis showed well preserved glandular and hair follicle elements but severe degenerative often coagulative change in the collagen (Fornari 1954)

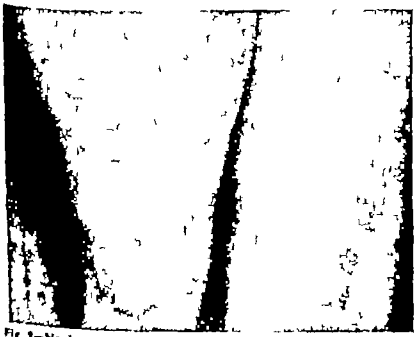

Fig 9—Naples accident: body C. Pattern of skin darkening on front of thighs with "shadowing" of garments.

NAPLES ACCIDENT

3 of the bodies recovered had obvious skin changes quite different from those described in the victims of the previous crash. In each case the lesions appeared as a brown or smoky coloration in exposed parts of the body with sharply defined margins corresponding to the edges of garments In 1 body the darkened areas were the back and front of the trunk and thighs, with an encircling pale band corresponding to the level of the waistband of the skirt the darkening was sharply limited above at a level corresponding to the lower edge of a brassiere while the lower edge was not well defined In a second case (adult male) the back showed a clear T-shaped pale band underlying the waist and perineal straps of a patent suspensory garment The third body showed very clearly intense darkening of the areas between stocking tops and corset, with pale bands corresponding to the outlines of the suspenders (fig 9) There was in this case less intense darkening of areas underlying the main parts of the stockings, and sparing of the skin under the reinforced band at the upper end This "shadowing" of garments was less marked on the back than the front of the thighs The 2 remaining bodies showed a slight darkening of the skin of the legs, not clearly delineated above but cut off sharply at the level of the shoes in one case, and the level of short socks in the other The clothes bore no signs of fire or chemical staining The affected areas of the skin were not those one would normally expect to find "tanned" by sun bathing during life

Histologically the skin was normal In view of the long interval between death and necropsy the preservation was remarkably good Pigment granules were visible in the normal situation in skin from both pale and dark areas of the bodies, with no visible difference in quality *quantity, or distribution*

CAUSATION

The first consideration appears to be whether the two types of lesions (called for convenience "burns" and "darkening" in the Elba and Naples accidents respectively) can be attributed to the same cause or causes In studying this matter the following conclusions were reached:

(1) Neither type of lesion appeared to be familiar to forensic pathologists, and no immediate cause could be assigned to either when first seen.

(2) In both accidents most of the bodies were affected but the types of skin change were quite distinct—i.e., "burns" only in Elba bodies "darkening" only in the Naples bodies

(3) There was a fundamental difference in distribution of lesions "burns" affecting predominantly clothed areas, and "darkening" involving exposed skin only

(4) There was histological evidence of tissue destruction in the "burns" only

(5) In neither case was there any evidence of exposure to flame or searing temperatures.

In view of these facts it was felt that separate causes are possible and indeed probable for the different types of lesion Was there any factor present in one accident and absent in the other which might give a clue to the ætiology of the injuries? The only obvious difference was that the length of time that the bodies were in the sea differed greatly four hours at Elba and twenty two hours at Naples

Ætiology of "Burns"

In the course of discussions with Dr Teare the following possible causes were considered

(1) *Contact with hot metallic surfaces not hot enough or acting long enough to cause singeing*—This is improbable because it would imply that all but 2 of the bodies lay oriented back

down to the surface, which was uniformly heated to a sub singeing temperature, or that contact was limited to a short time in all the cases It also seems unlikely that in only 1 instance was an unclothed area burnt in spite of such parts being exposed more directly to any heat source

(2) *Contact with hot liquid or vapour in the aircraft*—The location of the lesions would again imply similar orientation of 13 of the 15 victims Of the possible liquids, engine oil, tea, and coffee have been excluded by chemical examination of the clothing Hydraulic fluid, though not definitely ruled out, is a most unlikely agent when its volume, temperature, area of spread, and access to the passenger cabin are considered. Once more the sparing of exposed parts is unexplained by this theory

(3) *Abrasion on impact*—This is considered to be ruled out on the basis of absence in the Naples victims, the distribution of the lesions, and the macroscopical and microscopical appearances

(4) *Exposure to high intensity flash from an aircraft fire during free fall of the bodies*—This is unlikely, and is incompatible with the location of injury in covered areas

(5) *Fall through flame from burning fuel in or near the aircraft*—This cannot be reconciled with the absence of scorching or charring of clothes and skin

(6) *Chemical burning*—Battery fluid can be excluded on the grounds of lack of access and failure of chemical tests on clothing Two highly suspect substances known to be present are kerosene fuel (paraffin) and methyl bromide (used in fire extinguishers in engine and equipment bays of the aircraft) The former was present in large quantities and is known to be a skin irritant under some circumstances, moreover, the clothing on the bodies smelt strongly of kerosene However, exposure of skin to kerosene and sea water soaked clothing produces no lesions, at least during the relevant period Methyl bromide can certainly burn living skin (von Oettingen 1946), and, being highly volatile, is difficult to detect in clothing However, in experiments made at the R.A.F Institute of Pathology and Tropical Medicine only 1 of several freshly killed guineapigs showed any reaction to being clothed over the shaved abdomen, sprayed with kerosene and methyl bromide, and then floated in sea water The solitary finding was slight congestion of the dermal capillaries, with occasional extravasated red cells—quite unlike the human material from Elba

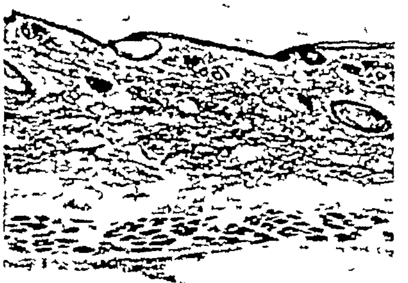

Fig 10—Guineapig skin normal appearance. (Hæmatoxylin and eosin ×28)

(7) *Contact with a surface layer of sea water heated by burning kerosene*—Experiments suggest that this is the most probable explanation of these " burns " A film of kerosene burning on the surface of a large expanse of water produces temperatures of 100°C at surface level, 70–100°C at a depth of $^1/_4$ inch, 30–50°C at a depth of $^1/_2$ inch, and no change (18°C) at or below 1 inch from the surface (Royal Aircraft Establishment 1954) In experiments at Farnborough, recently killed guinea pigs were " clothed " with bands of various types of material over depilated abdominal areas and allowed to float on the surface of a water tank 35 ft in diameter Kerosene was poured on to the surface and ignited In spite of all the bodies having been enveloped in an unapproachable conflagration (air temperatures of 500°C $^1/_2$ inch above the water surface) the only sign of their having been exposed to fire was scorching of the distal parts of the limbs and ears in 3 of 6 animals It was apparent that these relatively rigid members projected above the water in a way unlikely to be paralleled by any portion of the human anatomy None of the clothing was burned Underneath the fabric, which was in most cases stained in a similar way to the garments seen at Elba, pinkish areas of indurated skin could be seen and palpated These ar [illegible] e or both flanks, corresponded to the uppermost [illegible] the floating guineapig in each case Comparison [illegible] l preparations of the skin from affected and [illegible] showed relatively little change of the epidermis but very pronounced swelling and coagulative necrosis of the dermal collagen (figs 10 and 11) Glandular structures and hair follicles were still recognisable

It appears that clothed bodies, floating in water where a kerosene film is burning, may be scalded by the heated surface layer of water about $^1/_2$ inch in depth, without singeing or charring of the clothing or hair, provided that the garments are wet and that no part projects above the surface

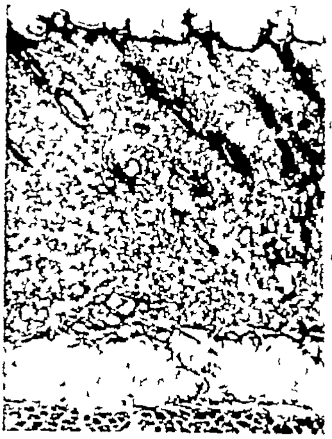

Fig 11—Skin from flank of dead guineapig floated in water covered by burning kerosene, showing dermal thickening and coagulative necrosis (Hæmatoxylin and eosin ×28)

Little is known of the orientation of a floating freshly dead cadaver killed by means other than drowning It is most probable that the position is face down, with the limbs and head dependent It was recorded by those who recovered the bodies at Elba and Naples that in each case all but one of the bodies was floating back uppermost In such circumstances the scalded areas in a person floating in a kerosene fire would correspond closely to those areas of the back predominantly affected in the Elba victims The unidentified yellow stains on the clothing are, of course, also accounted for by this theory, but their exact nature remains obscure.

Ætiology of " Darkening "

This type of skin marking could be ascribed to one or more of three fundamental types of change application of an exogenous coloured material, formation of an intradermal or intra epidermal coloured substance from degradation of structural elements, or intensification of the normal pigment of the skin

An exogenous coloured material was excluded by the failure of various solvents to remove the colouring, and the absence, in unstained frozen sections, of any apparent surface deposit of coloured matter In stained and unstained sections there was no evidence of structural or colour abnormalities other than slight post mortem change which was the same in dark and pale areas Darkening of pre existing melanin in human skin under certain conditions, which could occur in life or after death, was described by Meirowsky (1909) This and subsequent work (Lignac 1923, Miescher and Minder 1939, Blum 1948) has shown that pigment can be darkened in dead skin by exposure to sunlight or to long wave ultraviolet rays over the 3000–4200 Å range, and by maintaining pieces of dead skin at a temperature of 56°C for one to three days

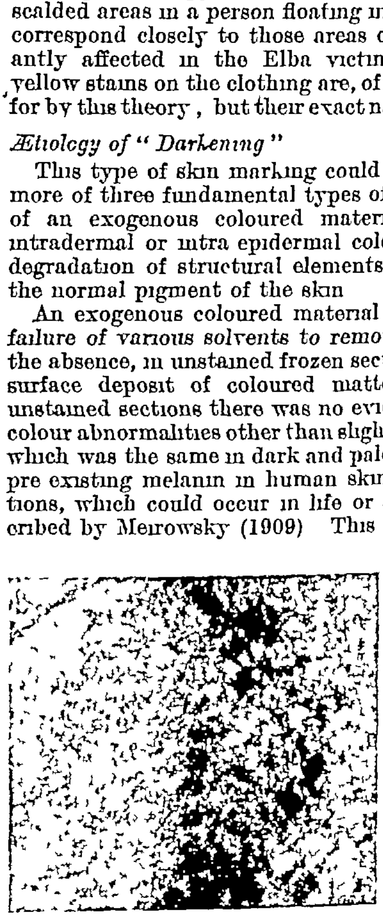

Fig 12—Pigment darkened in recently dead skin of human thigh after six hours' exposure to emission of carbon-arc. Left half of specimen was shielded from light. (×2 approx)

In experiments made at the National Physical

Laboratory with the kind coöperation of Mr J S Preston and others in the Radiant Energy Section pieces of human skin which had been dead for about twelve hours were exposed to a light source (a cored carbon arc) with an emission similar in long wave ultraviolet content and intensity to summer sunshine Part of each piece of skin was shielded with aluminium foil Well defined darkening of the pigment was produced after two and a half hours exposure and was little changed by prolongation to six hours (fig 12)

It is difficult to imagine circumstances in the accident which would give rise to a short-duration 'flash emission of sufficient energy to cause the skin changes seen in the Naples bodies It is known that they floated in the sea for about twenty two hours, including the greater part of a clear sunny day, and in all probability the skin markings were due to post mortem darkening of pigment in unclothed areas as a result of ultraviolet irradiation The sites of maximal intensity of pigmentation were as might be expected from the attitude of the bodies when found

Conclusions

Reconstruction of the events from medical evidence alone must of necessity, be largely a question of relative probabilities but the condition of the bodies recovered from the sea can be explained most satisfactorily on the basis that the injuries were inflicted in three distinct phases in the aircraft, on impact with the sea, and while the bodies were floating in the water

Head injuries including multiple fractures of the vault and base of the skull were an outstanding feature Extravasations of blood showed that most of these occurred in life The observations of Merkel (1920) and Lemke (1928) on deaths from jumping into water show that head injuries of this type do not occur regularly in such cases and our experimental findings are in full agreement with this. We conclude that the head injuries together with certain abrasions and at least some fractures of the thoracic cage were acquired in the aircraft apparently as the result of an extremely violent upward and forward displacement of the seated occupants at the moment of the initial failure Safety belts would not have been fastened half an hour after take off, and these injuries could be expected to result from violent impact with the inside of the aircraft and its furnishings They were alone sufficient to cause death and were presumably the source of fat embolism in those cases in which it was found This violent movement may have contributed to the internal injuries but is not thought to have been the major cause

Initially there was much speculation about the origin of the displacement forces Calculations by aerodynamicists showed sudden deviation from the line of flight due to malfunction or misuse of controls unlikely to be sufficiently violent to cause such numerous skull fractures The latent energy in a pressurised cabin of large volume has been calculated as being equivalent to that contained in about 100 lb of high explosive (Walker 1950) and the hazard to occupants *of displacement by the rush of* escaping air during sudden depressurisation has long been appreciated (Sweeney 1944 Fulton 1948) The dramatic effects of such failure have been illustrated by model cabin tests with anthropomorphic dummies at the Royal Aircraft Establishment We conclude that the most probable cause of the upward and forward motion imparted to the occupants of the aircraft was a sudden cabin failure In fact reconstruction of the Elba wreckage demonstrated beyond doubt that an initial structural failure of this kind did take place and extensive examination and testing of Comet aircraft have supported the belief already expressed that the Naples accident followed a similar pattern There is no definite evidence to show whether or not the lungs were damaged by the explosive decompression but for reasons already given this is considered to be unlikely

As the aircraft broke apart all or most of the passengers were ejected, presumably at different altitudes and fell into the sea All the available evidence indicates that forces generated by impact with a water surface after such a fall must cause grave injury to internal organs The nature of the internal injuries in the bodies recovered including the pulmonary lesions is consistent with their having been caused for the most part in this way In the circumstances any pre-existing visceral damage due to explosive decompression or to impact within the aircraft could not be identified Other injuries probably received at the same time include fractures of the limb bones and spine and further damage to the thoracic cage Experimental dropping of full scale clothed dummies has confirmed that impact with the sea rather than free fall through the air was also responsible for the extensive loss of clothing (Royal Aircraft Establishment 1954) It is just conceivable that a few passengers remained within a segment of the fuselage until it hit the sea This is unlikely to have afforded much protection but might possibly explain why some of the bodies, all from rearmost seats had retained most of their clothing

Finally, while floating on the sea 14 of the Elba bodies were subjected to post mortem scalding of the skin It is improbable that they fell into an existing kerosene fire, because there was no singeing or burning of their clothing or hair ; more likely the fire started after they had fallen into an area covered by a kerosene film The bodies from Naples showed no scalds but instead a pattern of post mortem darkening of the pigment (the Meirowsky phenomenon) as the result of exposure to the bright sunshine of April 9

We are greatly indebted to Prof A Fornari of the Institute of Forensic Medicine in the University of Pisa, and to Dr Donald Teare for allowing us access to the necropsy material and for their advice and coöperation throughout the investigation. We wish to acknowledge also the coöperation of the director and staff of the Royal Aircraft Establishment ; and help in the experiments from colleagues at the Institute of Aviation Medicine We are grateful to Sir William Penney for allowing us to quote from unpublished work and to the Commissioner of Metropolitan Police for the photograph reproduced as fig 9 Finally we are indebted to the Director General R.A F Medical Services for permission to publish.

COMPLICATIONS OF CHLORPROMAZINE THERAPY IN 800 MENTAL-HOSPITAL PATIENTS

J LOMAS
B.A , M B Camb , D P M

SENIOR REGISTRAR

MORRIS MARKOWE
M D Lond , D P H , D P.M
CONSULTANT PSYCHIATRIST

SPRINGFIELD HOSPITAL, LONDON

CHLORPROMAZINE has been increasingly used in both psychiatry and anæsthetics since 1951 The early investigations of Courvoisier et al (1953) into its pharmacological effects on animals suggested that it was relatively non-toxic, but subsequent trials on man have not confirmed this, and Burn (1954) suggests that it is toxic to animals Complications have been reported which, though not perhaps justifying all the precautions advocated by the earlier workers suggest that great care should be taken in administering chlorpromazine

The complications can be divided into side effects and toxic reactions The side effects are usually due to the pharmacological action of chlorpromazine on the autonomic nervous system and are therefore necessary concomitants of the treatment, whereas the toxic reactions are observed in relatively few patients and are due to idiosyncrasy The distinction is not absolute, there being some overlap between the two types of complication

Side-effects Previously Reported

Cardiovascular system —The most important side effects concern the cardiovascular system Tachycardia and pallor are almost unavoidable, at least in the early stages of treatment, and are sometimes associated with a fall in blood pressure which may give rise to vertigo, weakness, and syncope For this reason the earlier workers advocated rest in bed in the initial stages of treatment (Delay and Deniker 1952, Sigwald and Bouttier 1953a, Anton Stephens 1954), but this is now considered unnecessary (Garmany et al 1954, Lomas 1955)

Gastro intestinal tract —Gastro intestinal disturbances are common, dryness of the mouth is mentioned in almost all reports, and constipation, diarrhœa, nausea, and vomiting are common Nausea and vomiting are perhaps surprising in view of the proved anti emetic action of chlorpromazine (Friend and Cummins 1953, Moyer et al 1954a) Lehmann and Hanrahan (1954) report an increase in appetite and a gain in weight, these changes Elkes and Elkes (1954) correlate with clinical improvement

Respiration —Courvoisier et al (1953) found that small doses stimulated, and larger doses depressed respiration in rabbits This difference of action in different dosages may explain the conflicting reports on the effects of chlorpromazine on respiration in man Lehmann and Hanrahan (1954) found no change, Staehelin and Kielholz (1953) depression, and Bensoussan and Klein (1953) severe dyspnœa

Micturition —Lehmann and Hanrahan (1954) found an increased frequency of *micturition* but no other abnormality This is confirmed by Moyer et al (1954b)

Central nervous system —A parkinsonian like syndrome is reported by Lehmann and Hanrahan (1954), Azima and Ogle (1954), and Anton Stephens (1954), who, probably correctly, attribute it to overdosage Anton Stephens (1954) and Winkelman (1954) report an increased tendency to dream.

Local irritation —Intramuscular chlorpromazine produces local irritation *at the site of the injection*, this may cause considerable discomfort (Anton Stephens 1954, Winkelman 1954 Charatan 1954), which can be minimised by dilut *the injection* (Deschamps 1952, Staehelin and Kielholz 195 Arnold et al. 1953)

There is no change in the blood sugar level (Staehelin and Kielholz 1953, Lancaster and Jones 1954), electrocardiogra (Friend and Cummins 1953 Moyer et al 1954b), or elect encephalogram (Terzian 1952, Flügel 1953)

Toxic Reactions Previously Reported

Acute toxic reactions have been singularly rare, but Deni (cited by Winkelman 1954) had a patient who attemp suicide by taking 750 mg of chlorpromazine and lapsed into coma but recovered uneventfully within a few days. Charatan (1954) and Lomas (1955) recorded 1 and 9 deaths respectively in their series, but in none of these cases could chlorpromazine be implicated with any conviction In 2 patients, however, both of whom had liver disease, chlorpromazine was considered to be at least a contributory cause of death (Boardman 19 Deschamps 1952)

Hepatitis

The most serious complication is toxic hepatitis Garm et al (1954) reported abnormal liver function tests, and b salts in the urine, but no manifest jaundice in 3 of 29 ca Charatan (1954) had 1 case in 42, and Winkelman (1954) in 142 (in 1 of these liver biopsy showed chronic liver dama Lehmann and Hanrahan (1954) treated frank jaundice in of their 71 cases but reported slightly abnormal liver funct tests in 50%

On the other hand, Elkes and Elkes (1954) had 1 case jaundice in 27 but found no abnormality in liver funct tests done at fortnightly intervals in the 26 other cases, Moyer et al (1954b) found hepatic function normal in cases Azima and Ogle (1954) report 8 cases in 100, but th was an outbreak of mild infective hepatitis at the tim Eagles (1955) reports 3 cases in 18—the highest incidence recorded Both Garmany *et al* (1954) and Elkes and E (1954) continued treatment with chlorpromazine after interval and observed no untoward effects

Blood Picture

Rizzo and Russo (1953), in carefully conducted inve gations on 15 patients, found after a single injection chlorpromazine an almost constant slight decrease in number of red cells and in the amount of hæmoglobin, leucopenia, lymphocytosis, neutropenia, and eosinop This change was observed three hours after the injection. the blood tended to return to normal in twelve ho Similarly the erythrocyte sedimentation rate (E.S.R.) three hours after the injection and tended to return to nor in twelve hours This difference in the findings after three after twelve hours may possibly explain the different res of other workers

Friend and Cummins (1953), Lehmann and Hanra (1954), and Charatan (1954) found no change in the bl picture Elkes and Elkes (1954), who did full blood-co fortnightly, found polychromatic cells with basophil stippling in 1 case and neutropenia in 1 other Staehelin and Kielholz (1953) and Delay et al (1952) agreed with Rizzo and Ru (1953) in finding an initial neutropenia returning rapidly normal, but found no abnormality in the red-cell co Anton Stephens (1954), on the other hand, found a leucop in half his cases and a raised E S.R in almost all Lo (1954) reports 1 case of agranulocytosis, and F J A (personal communication) mentions 8 others in the Unit States Of these, only 1 has so far been published (Bo 1955), of the unpublished cases 1 proved fatal but all the others were cured with corticotrophin

Pyrexia in the first few days treatment has been noticed y most workers (Staehelin and Kielholz 1953 Garmany et al. 1954 Lehmann and Hanrahan 1954) Sigwald and Bouttier 1954b) and Charatan (1954) attribute it to local inflammation it the site of injection.

Skin eruptions either urticarial or maculopapular are eported by Broussolle and Hamoneau (1953) Azima and gle (1954) Winkelman (1954) and Lehmann and Hanrahan 1954), the last-named in 13% of their cases.

Epileptic fits —Anton-Stephens (1954) mentions that 1 st leucotomy patient had epileptic fits but attaches no gnificance to this finding Lehmann and Hanrahan (1954) te that 1 patient who had been given 2 ml. of nikethamide fter chlorpromazine developed status epilepticus

Present Survey

Our report is based on 800 patients (260 male and 40 female) treated with chlorpromazine in Springfield Hospital between November 1953 and the end of 1954 e patients were not questioned about any untoward fects hence any complications noted were either a ult of spontaneous complaint by the patients or *served by the nurses and doctors.*

Toxic effects were all recorded on a pro forma with a te of the dosage, total amount of chlorpromazine ministered at the time of the reaction duration of atment and any possible alternative ætiology to lorpromazine.

Though all types of mental cases were treated the at majority were *acute or chronic psychoses* The age varied considerably from patient to patient but e most commonly adopted plan was to start with 150 daily and to increase rapidly to 300 mg daily The seriously disturbed patients received smaller doses, d a few patients had their dosage increased to 800 mg ily The duration of treatment varied from a few eks to several months The great majority of patients eived the chlorpromazine by mouth and were treated bulant from the start A minority underwent electro vulsion therapy concurrently and most patients were eiving barbiturate sedation No other form of rapy could account for the toxic reactions

SIDE EFFECTS

rdiovascular System

The tachycardia noted by most previous workers was esent also in this series and when looked for specifi lly was found in almost all patients in the initial ages of treatment. Only extremely rarely was it ociated with palpitations or did it give rise to any ontaneous complaint from the patient Pallor was s common.

Minor hypotensive symptoms were complained of by me patients in the early stages of treatment but ncopal attacks were extremely rare With 1 exception e few which did occur were all in elderly or arterio rotic patients For this reason it was considered necessary to treat patients in bed unless their mental ndition necessitated it with the *exception of the* derly and the arteriosclerotic

Gastro intestinal tract —Of gastro intestinal complaints ness of the mouth and constipation were far the most mmon Nausea vomiting, and diarrhœa occurred too rely for chlorpromazine to be implicated A pro unced increase in appetite and weight were noted, rticularly in patients given chlorpromazine for a long me One patient who had not previously shown onounced fluctuations in weight gained 5 st in as any months

espiration —No respiratory anomalies were noted

Micturition —Frequency of micturition was observed. casional incontinence of urine and more rarely still of ces occurred Incontinence seems to be due to over sage because it rapidly disappears if the dosage is educed

Central nervous system —The parkinsonian like syn drome was also occasionally noted and similarly responded to a reduction in dosage

Local irritation at the site of injection occurred but was not of great importance in this series because the great majority of patients received the chlorpromazine by mouth

Both subjective complaints and observed disturbances were much less common in disturbed psychotic patients than in others and the more chronic the psychosis the less was the incidence of side effects. The only exception to this was the gain in weight, which took place in all types of patient if they were treated with chlorpromazine for a long time The predominance of psychotic patients in this series may explain the altered emphasis on the various side-effects from that of other investigators

TOXIC REACTIONS

The total number of toxic reactions recorded in the 800 patients was 59 (7.4%) Of these 48 (8.9%) occurred among the women and only 11 (4.2%) among the men. This difference varies in the different toxic reactions (see below)

Jaundice

All patients in whom jaundice arose during chlor promazine therapy are included no cases arose after completion of therapy Unfortunately the study is clouded by the coincidental appearance of infective hepatitis in patients not receiving chlorpromazine The two conditions were clinically and biochemically indistin guishable but the incidence was significantly higher in the chlorpromazine population only 3 cases occurring in the rest of the hospital population of over 2000 patients

There were 11 cases of chlorpromazine jaundice (1·4%), 4 male (1.5%) and 7 female (1.3%) No age group was immune At the onset chlorpromazine had been administered for from sixteen to thirty three days (mean twenty two) The daily dosage at that time and the total quantity administered varied widely and were not significant All the patients received the chlor promazine by mouth but 5 had started with intra muscular injections for a few days The appearance of jaundice was regarded as an absolute contra indication to the further use of chlorpromazine The jaundice lasted from one to twenty six weeks but if the 2 most severe cases (in which the jaundice lasted thirteen and twenty six weeks) are excluded the mean duration was two weeks

In 7 instances icterus was the presenting symptom associated in 1 case with pyrexia and gastro intestinal disturbance and preceded by four days in 1 other case by ephemeral asymptomatic pyrexia It is possible that ephemeral pyrexia had been missed in other cases Prodromal fever and malaise lasting one or two days ushered in 3 further cases 1 of which had already shown a morbilliform rash for a week The remaining case showed gastro intestinal symptoms gradually remitting nine days before jaundice on the twenty second day 6 of the patients presenting with icterus felt relatively well at onset including the 1 fatal case Anorexia was severe in 2 other cases

During the jaundice itching was common the liver was somewhat enlarged and slightly tender; the stools varied in colour from normal to off white; and the urine contained bile salts and pigments

The 3 mildest cases were not studied biochemically In the 8 others thymol turbidity colloidal gold and Takata Ara reactions and plasma protein estimations showed no abnormality The plasma alkaline phospha tase and serum bilirubin levels and the bromsulphalein clearance (when tested) showed consistent changes which reflected the *clinical state* The alkaline phosphatase showed peak values of 15-70 King Armstrong units per 100 ml (normal 2-12) and the serum bilirubin 3 23 mg per 100 ml (normal 0 5) The "direct" component of the serum-bilirubin was invariably 2–2½ times as great as the "indirect"

9 cases ran an uneventful course to recovery Of the 2 other patients 1, a chronic encephalitic, recovered after a stormy twenty six weeks but five months after clinical recovery still has an alkaline phosphatase level of 45 King-Armstrong units and bromsulphalein clearance of 83% only (normal 95%), the other patient, who had chronic rheumatic heart-disease, died after thirteen weeks' remittent illness (Boardman 1954)

Clinically and biochemically the jaundice is of obstructive type, but the liver in the fatal case showed central necrosis and biliary stasis, severe lobular atrophy, relative preservation of portal areas, and absence of exudate, which were interpreted as "subacute toxic hepatitis of blood borne type" The ante-mortem passive congestion of the liver did, of course, contribute to a significant degree to the central necrosis

Blood Picture

Routine blood counts were done weekly on 25 patients throughout the course of chlorpromazine No consistent general depression or stimulation of hæmopoietic tissue was found The case of agranulocytosis has already been described (Lomas 1954), where the white cell count decreased to 400 per c mm but rapidly increased to 5300 per c mm in ten days after the chlorpromazine was withheld In 4 cases there was a moderate leucocytosis increasing to a maximum in the third or fourth week of treatment, followed by a gradual decrease One case with a leucopenia of 2000 white cells per c mm was noted in the fourth week, but this soon cleared when chlorpromazine was withheld In another case a leucopenia of 3000 white cells per c mm was noted in the fifth week, but subsequent counts were within normal limits This patient had been diagnosed two years previously as having aplastic anæmia but had recovered, and the leucopenia may have been due to abnormally sensitive bone-marrow A microcytic hypochromic anæmia had been noted, with a decrease in the number of red cells from 4,680,000 to 3,000,000 per c mm by the fifth week

In more than half the cases the E S R rose to a maximum by the fourth week and then fell gradually, with a secondary rise in the seventh or eighth week in a minority There was no appreciable change in the remainder

Blood studies in 6 of the skin reactions showed definite eosinophilia (13% and 7%) in 2 These cases also showed mild leucocytosis of 11,450 and 13,600 per c mm, the eosinophil-counts being 1488 and 952 per c mm respectively Such responses, in conjunction with the clinical pictures, suggest either a hypersensitivity reaction or depression of the adrenocortical hormones

Studies of the pyrexial cases showed moderate neutrophil leucocytosis in 2 patients

Skin Reactions and Œdema

These two reactions are discussed together because they so often occurred in association 22 cases (2 8%) were noted, 19 (3 5%) among the women and only 3 (1 2%) in the men 10 cases showed skin reaction and œdema mainly of the face but sometimes of the extremities as well 8 showed skin reactions only, and 4 œdema alone 3 cases had a slightly raised temperature, but the rest were apyrexial

The skin reactions were of two distinct types The first was an erythema confined to the exposed parts of the body and noted in 8 cases It occurred at any stage in treatment and on various dosages, but 6 of the 8 cases developed in August and the 2 others in April and June This reaction was regarded as due to photosensitivity, but similar reactions among the rest of the hospital
ts, owing to the deficiency of sunlight last summer,
emely rare
second reaction, observed in 14 patients, was a
orm eruption over the entire body It came on between the fourteenth and thirty-fifth days of treatme except in 2 cases, and most of the cases arose about t beginning of the fourth week Most of the patien were receiving 300 mg daily at the time, which wou be the expected daily dosage at this stage of treatmen The total dosage received varied considerably

The rash cleared up uneventfully in about a wee whether treatment with chlorpromazine was maintain or not, and did not recur when treatment was resume Generally, when there was no œdema, treatment w continued, but, if there was any œdema, treatment wa stopped temporarily

Pyrexia

Pyrexia was observed in 16 patients (2%), all of the female, in whom the incidence was 3% The pyrexia w generally low-grade (99–100°F) but occasionally rose 105°F, and usually lasted from twenty four to forty-eig hours, whether or not treatment with chlorpromazi was continued, but rarely lasted a week There was relationship either to the dosage at the time of occurren to the total dosage, or to the mode of administration, b with 1 exception it occurred between the fifth and thi teenth days of treatment, with the highest inciden about the beginning of the second week The 1 exce tion occurred on the thirty third day of treatment a was so unusual as to give rise to doubt about whethe chlorpromazine could be implicated

Pyrexia alone was rarely considered to be a contr indication to continuing treatment with chlorpromaz

Epileptic Fits

Epileptic fits occurred in 10 patients (1 3%) 4 (1 5% men and 6 (1 1%) women and had no relationship eith to dosage at the time, to total dosage, or to duration treatment

6 of the 10 patients had had leucotomy, and 4 of the had had previous fits immediately after the operation b not for many years The 2 others had not had an previous fits None of them has had a fit since treatmen with chlorpromazine was discontinued

Of the 4 other patients 1 had arteriosclerotic dementi and although he had had no fits before treatment wit chlorpromazine he continued to have them after it w discontinued, 1 was demented as a result of a severe he injury and had a succession of epileptic fits only while was on treatment, 1 was schizophrenic and had ha occasional fits in the remote past but none for severa years before treatment with chlorpromazine and no after, and 1 was a schizophrenic who had no fits eithe before or after treatment with chlorpromazine

In only 1 of the 10 patients who had epileptic had no tendency to epilepsy been observed, but in all them fits were very rare, had been absent for a long tim and, with 1 exception, have not recurred since treatm with chlorpromazine was stopped The fits were regard as a contra-indication to continuing treatment wi chlorpromazine

Discussion

Although the side effects (as distinguished from tox reactions) which may be due to chlorpromazine a numerous, the only one of any real significance is hyp tension, and, if due caution is taken in elderly patien and those with cardiovascular dysfunction, this on rarely causes any but minor symptoms It is met wi especially during the early stages of treatment wi chlorpromazine and when the dose is increased, a thus the risk is negligible

Of the toxic reactions, jaundice and the rare blo dyscrasias are the most important, because both may b fatal Death due to jaundice has so far only be reported in cases with previous liver dysfunction, the fore this risk may be avoided by regarding such cas contra indicating chlorpromazine treatment Previ bone marrow dysfunction also contra indicates chlo promazine treatment

Whereas the dosage at the time of the toxic reaction the total dosage, and the method of administration appeared to be of no significance the duration of treatment before the reaction was much more constant The greatest incidence of pyrexia was at the beginning of the second week and both jaundice and skin reactions came on about two weeks later Only in the case of epileptic fits was this time relationship not observed Toxic reactions of any sort, again with the exception of epileptic fits, were very rare *after the end of the fifth week* although a large number of cases were treated with chlorpromazine longer than this

There are two possible explanations Some people may be particularly susceptible to chlorpromazine in which case they might be expected to show early signs of toxicity but then they would also be expected to show other signs of intolerance and this was not observed The other and more probable explanation is that the toxic effects are due to sensitisation though this is curious *in view of the known antihistaminic properties of* chlorpromazine Some support is lent to this suggestion by the development of eosinophilia in a few cases Further in those cases in which treatment with chlorpromazine was continued regardless of the toxic reaction the toxic symptoms subsided spontaneously and rapidly The sensitisation hypothesis is therefore worth further investigation

The fact that the epileptic fits had no relationship either to dosage or to duration of treatment suggests that chlorpromazine has epileptogenic properties which may lead to manifest fits in susceptible people This is to be the subject of a special study

Summary and Conclusions

The complications noted in the course of treating 800 patients with chlorpromazine are classified Such complications *may be divided into side-effects and toxic* reactions.

Of the side-effects hypotension is the only one requiring special precautions and then only in the aged and those with cardiovascular dysfunction

Jaundice blood dyscrasias skin reactions and œdema pyrexia and epileptic fits all occurred as toxic manifestations. Of these jaundice and blood dyscrasias may prove fatal and are regarded as being absolute contraindications to continuing treatment with chlorpromazine Previous liver dysfunction may predispose to jaundice and therefore should also be regarded as a contraindication to such treatment

With the exception of epileptic fits the time of occurrence of all toxic manifestations had a definite relationship to the duration of treatment but not to the dosage at the time or to the total dosage of chlorpromazine

In view of this finding and the occurrence of eosinophilia in some cases the toxic reactions are probably due to sensitisation

Epileptic fits occurred mainly in post leucotomy patients and in only 1 case were no predisposing factors detected Therefore chlorpromazine may have epileptogenic properties which may cause manifest fits in susceptible people

ADDENDUM

Since this article was written J R Tasker (*Brit med* J 1955 i, 930) has reported a further fatal case of agranulocytosis due to chlorpromazine

The *treatment of writer s cramp is recognised as* most discouraging to patient and therapeutist alike Though included nosologically with the motor neuroses writer s cramp has hitherto defied any satisfactory ætiological interpretation in terms acceptable to neurologists psychiatrists, and psychologists

Culpin (1931) and Pai (1947) thought that writer s cramp occurred *merely as one form of disablement* in patients of psychoneurotic constitution and Glover (1949) considered it to be a typical example of conversion hysteria but Critchley (1954) affirming that writer s cramp constitutes a specific impairment of motor skill, was at pains to point out that to look upon the craft palsies as problems in psychopathology has not proved satisfying even to psychiatrists

In a recent neurological and psychological re-examination of 20 cases of writer s cramp 1 typist s cramp *and 1 violinist s cramp (to be reported)* we *concluded that* although some of the patients could be regarded as having psychoneurotic tendencies many showed no evidence of psychological disorder Indeed the pattern of mental and emotional make up of these patients exhibited the widest possible variations These observations led us to the tentative conclusion that whatever the origin of writer s cramp its persistence might be explained by the establishment of a conditioned reflex The resemblance between the writing in this condition and that observed in certain types of extrapyramidal disease invites the suggestion that this conditioning takes place at subcortical levels and the partial benefit conferred by the administration of benzhexol hydrochloride (Artane) affords some support for this suggestion It seemed from the clinical evidence that although the loss of acquired motor skill represents a reaction to a total situation involving the *act of writing the sensori* motor circuit could be regarded in terms of afferent stimulus and motor effect Close observation of the development of the cramp during the act of writing revealed that it tended to arise when the pen or else the writer s hand touched the writing surface and was then intensified by the movements of the fingers and thumb as *writing proceeded The trigger stimulus for the condi*tioned reflex should then be one or both of the following (1) tactual stimulus of the pen and (2) tactual stimulus of the hand touching the writing-surface The motor

effect varies from case to case but tends to have two principal components (1) a tremor of variable rate and amplitude, and (2) a spasm of the muscles of the hand, forearm, and even the upper arm, variable in its extent and intensity but invariably accompanied by excessive pressure of the thumb upon the pen

Proceeding on the assumption that a conditioning mechanism is at work we reasoned that it might be possible to disturb the reflex by the administration of a sensory counter stimulus whenever the motor effect took place After some tentative efforts with feed-back from needle electrodes placed in the muscles of the forearm, simpler techniques were evolved to deal with the tremor and the pressure of the thumb on the pen It was felt that by attacking these primary manifestations of the motor dysfunction we might break down the whole sensorimotor chain

To date we have completed treatment of 6 patients with writer's cramp* and 1 with typist's cramp 2 other patients with writer's cramp are still under treatment It seems appropriate to give in some detail the histories and course of 2 of the patients with writer's cramp and of the 1 case of typist's cramp, The 2 writer's cramp cases were selected because 1 had a definite history of psychiatric abnormality and the other was a man whose history and personality were devoid of recognisable psychological disturbance, and in both cases the disturbance of writing comprised both tremor and spasm The case of typist's cramp is interesting in illustrating a modification of the technique to suit a particular motor problem where the principal disorder was a flexor spasm of certain fingers

Writer's Cramp

Case 1—A female typist, aged 49, an intelligent but anxious woman who in the first interviews concealed many facts of her history, passing herself off as single when in fact she had been married and divorced, and had numerous social and personal disturbances in her life The evolution of her cramp was at once interesting and complex She took to bookkeeping at the age of 18, and for the next 26 years experienced no trouble with her writing although occupied for six hours each day in ledger work At 41 she took a different post as a typist, but it was only after three years of this that she developed severe pain in the right thumb Tenovaginitis was diagnosed At this time she had already begun to experience stiffness of the whole hand whenever she tried to do her shorthand, and, after an operation had been done to relieve the tenovaginitis, her shorthand became impossible She then became a copy typist Thereafter any attempt at writing produced the pain, cramp, and tremor In 1953, when she was 49, even copy typing produced cramp and pain in the muscles of the right hand, arm, and forearm Soon after, the cramp began to show itself in other similar movements, and when first seen in March, 1954, she had an almost constant spasm of the muscles of the right arm and hand An attempt to write produced a slow and painful exhibition

stared most unpleasant

Fig 1—Case 1 specimen of writing before (above) and after treatm

characteristic of writer's cramp She had been treated wi benzhexol hydrochloride without success, had receiv extensive courses of various sedatives, and had been advis to give up her work She had become exceedingly depres and anxious about her condition but was struggling to pe form her duties She subsequently left her work in June, 195 and review in August indicated a general increase in h depression and despondency, and the cramp and spasm the right arm had become continuous

Case 2—A male clerk, aged 31, noticed in June, 1 after 2 years in his present post, which involved writing 4–6 hours each day, that after writing for 5 minutes developed a tired feeling in the hand and forearm with trem On his continuing to write his arm rapidly became s his thumb tensed, his hand tended to turn over and writing became illegible Two weeks' holiday did not prod any change, and treatment with phenobarbitone and ben hexol hydrochloride proved unsuccessful In May, 1 he improved a little spontaneously in that the cramp te to develop after a longer interval and his writing was f legible There had been no discernible change in his perso domestic, or economic circumstances to explain this cha Re examination in August, 1954, showed that he wr slowly, stiffly, and with a tremor, but his writing was rat more legible than when he was first seen There were abnormal neurological signs, and no other movement affected

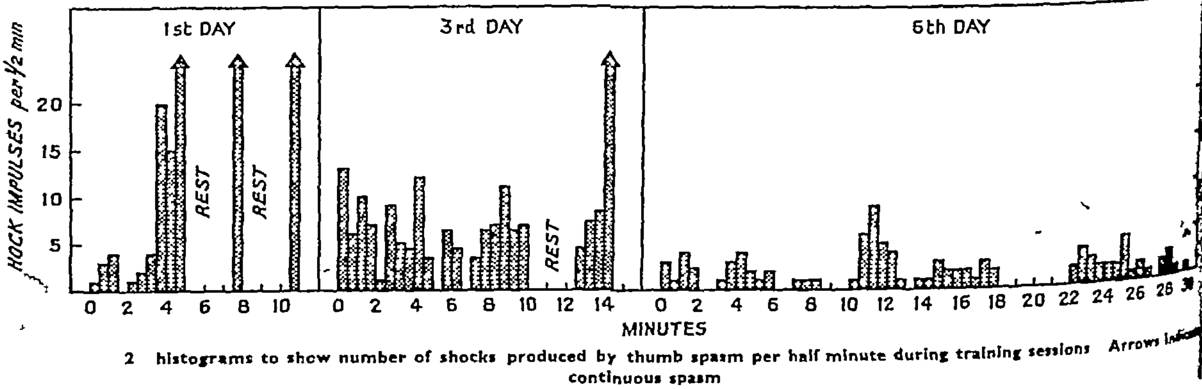
Methods and Results of Treatment of Writer's Cramp

As already stated, tremor and spasm are the t components of the motor disorder These were assail in the following way For the tremor a metal plate w drilled with nine holes ranging from $^{1}/_{2}$ to $^{1}/_{8}$ inch diameter The patient was required to insert a me stylo, held as a pen is held, into these holes, working fr larger to smaller as each size was successfully negoti Electrical circuits were arranged so that, whenever stylo touched the side of the holes, the patient recei a shock passing from palm to dorsum of the *left* hand

A second piece of training apparatus consisted strips of insulating tape arranged in straight, curv and zig zag patterns upon a metal plate and so dispo as to call for all the fundamental finger and hand mo ments required in writing Again circuits were so devi as to produce an electric shock for the patient sho

---

* A further patient has since been treated a man aged 53 with writer's cramp of 2 years duration Six training sessions produced complete cure which has been maintained for 1 month to date



2 histograms to show number of shocks produced by thumb spasm per half minute during training sessions Arrows in continuous spasm

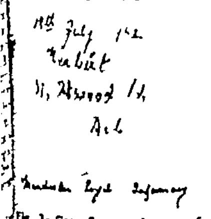
he deviate in any way in tracing the lined patterns with a metal stylo

The third retraining mechanism was an ordinary pen adapted in such a manner that excessive pressure of the writer's thumb would again produce a shock. This device was thus triggered by the spasm component of the disorder in which severe adduction and flexion of the thumb are so prominent.

Case 1.—Treatment was given on 15 successive days, apart from two omissions for Sundays, each session lasting about 30 minutes. The first five sessions were occupied with training on the holes and the tapes. Progress was fitful, but at the seventh session all the holes and the tapes were negotiated successfully, the tremor having disappeared. The next three sessions were spent in writing to dictation with the electrified pen. On the 13th and 14th days writing was almost normal with no evidence of tremor or spasm. On the 15th day she wrote for 15 minutes without effort and considered herself normal. When last seen three months after completion of the course she had maintained the improvement. She has now returned to work after an absence of three months. Fig 1 illustrates her writing before and after treatment.

Case 2.—Tremor was less prominent than spasm in this case. After only two sessions the holes and tapes were overcome and attention was turned to spasm. In six sessions the spasm was abolished and the patient considered himself completely relieved.

Fig 2 illustrates the progress made: it shows in graphic form the frequency per half minute of the sounds made by the shocking coil during writing in the first third and fifth of these sessions. It will be noted that on the first occasion the thumb went into continuous spasm after five minutes writing and that two rest periods did not bring relief. Four months after the end of the treatment this patient is still well and writing normally.



4th July 1952
Tablet
Aberdeen Royal Infirmary

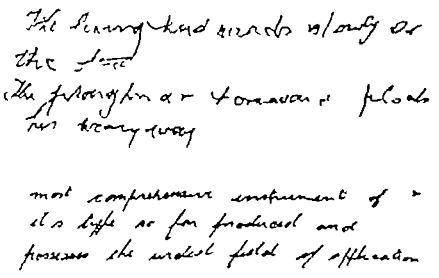
Fig. 3—Case 2: specimens of writing before (above) and after treatment.

Fig 3 illustrates his writing before and after treatment.

Cases 3, 4, 5, and 6 were all male and had had writers cramp for 3–10 years. After 3–5 weeks treatment they have shown degrees of improvement which we have estimated as 50–85% of their previous normal. The patient whose performance is estimated at only 50% considered himself cured and asked to discontinue treatment since his writing was now to him quite adequate. In the remaining cases the impairment of function comprises either a slight tremor or a lack of fluidity in the writing and although one of these patients writes for 7 hours each day in his work as a stockbroker's clerk he does experience some aching in his hand after 3 or 4 hours and so he has been assessed as an 80% improvement.

Typist's Cramp

Case 7.—A female shorthand typist aged 32. In 1949 during a period of domestic stress and after 13 years as a shorthand typist in an accountant's office she began to experience mild cramp in the left hand accompanied by extension of the left forefinger and adduction of the thumb. After 12 months the other fingers began to flex into the palm. In November 1951 she was seen at the Royal Infirmary and psychiatric interviews brought no benefit to her condition. In 1952 she changed her employment, and there was some improvement in her domestic background though there was still cause for anxiety. Her new work was more responsible and more arduous than her former employment and in August 1954 a similar but more painful affection of the right hand developed. After 10 minutes typing the index finger extended the thumb adducted and the remaining fingers flexed into the palm with such force as to produce bleeding if she continued. It was in this state that she returned for further advice.



The lowing herd winds slowly o'er the lea
The ploughman homeward plods his weary way
most comprehensive instrument of its type so far produced and possesses the widest field of application

Fig 4—Case 7: specimens of writing before (above) and after treatment.

Treatment and results.—For this case the apparatus was modified so that a small rubber pad was covered with an interweaving pattern of wire connected to the secondary winding of the induction coil. This pad was then fixed into the palm of the patient's right hand. Thus, any flexion of the fingers into the palm caused a mild shock. The patient was then instructed to type. In three sessions of twenty minutes duration on successive days a complete cure was achieved and has been maintained for 6 weeks.

Discussion

Although it is too early to be certain about the long term effects of treatment certain preliminary conclusions seem permissible in the light of these experiences. It is encouraging from the clinical point of view to have evolved a means of alleviating a condition which so often has proved intractable. One feels that in the event of relapse retraining may be of value, but this remains to be seen. Apart from this the physiological and pathological implications of the results of this form of treatment are of interest. We suggested above that the acquired motor skill of writing was susceptible to disorganisation by a process of conditioning and that irrespective of the initial cause of the disturbance the conditioned reflex would continue to operate making normal writing impossible. This heuristic approach to the problem led to the evolution of the method of treatment which really amounts to the extinction of the conditioned reflex which is disorganising the normal pattern of skilled volitional activity. The outcome of this technique of "deconditioning" as it may be called in patients who differed so much in mental and emotional constitution appears to afford support for our view of the physiological mechanism underlying writer's cramp. Further observation and experiments with the remaining patients are proceeding after which it may be possible to advance more definitive conclusions.

As regards the technique of treatment it may be suggested that the apparatus merely represents a symbol or a focus for psychotherapy. This suggestion is difficult to refute categorically but several of the patients had previously had psychotherapy without benefit and the courses of treatment were arranged so that each patient received treatment sessions from both of us. We feel that this type of therapy can be conducted by anyone with sufficient understanding of the mechanical nature of the disorder to be able to apply the various retraining exercises and that the psychological element in the treatment is relatively unimportant.

The patients were under the care of Dr Fergus R. Ferguson to whom we are further indebted for helpful criticism.

ROUTINE PREOPERATIVE CHEST RADIOGRAPHY

ANALYSIS OF 1000 CASES

R E LODER

M A., M B Camb , F F A R C S

CONSULTANT ANÆSTHETIST, PETERBOROUGH MEMORIAL HOSPITAL, NORTHANTS

MASS miniature radiography has shown a small proportion of the public to have undiagnosed pulmonary disease without any specific signs on clinical examination It is therefore advisable to radiograph the chest of every patient admitted for non emergency surgery

The main difficulty about routine chest radiography in the past has been that of expense because 17 × 14 in films cost 3s 8d each When, however, this hospital obtained a 5×4 in radiographic camera, the price of each chest film was reduced to just under 5d With the permission of the consultant radiologist and the willing cooperation of the radiographers and nurses, the following routine was instituted

Routine

Since often the patients were operated on the day after admission, there was no time for the usual procedure of filling in all details on a request form and of receiving a signed report back in the wards To prevent any delay the sister or the nurse admitting the patient to the ward filled in the request form as a "routine preop" The patient was radiographed the same day, and the film was inspected by the radiologist Abnormal findings were communicated immediately by telephone to the anæsthetist and discussed between him and the radiologist, the patient was re-examined, and, if necessary, a decision to postpone operation was conveyed to the surgical department concerned

Analysis

The radiographs were taken between July and December, 1954, and of the 1000 patients in this analysis 447 were male and 553 were female

Age groups

The numbers of cases in the different decades were as follows

Years	0–9	10–19	20–29	30–39	40–49	50–59	60–69	70–79	80 or more
Cases	263	120	111	124	157	97	80	38	10

Proposed Operations

General surgical operations numbered 233, including 43 major abdominal operations

Ear, nose, and throat operations numbered 347, including 189 removals of tonsil and adenoid, 15 radical mastoidectomies, and 29 submucous resections of nasal septa

Gynæcological operations numbered 175, including 24 hysterectomies and 35 pelvic-floor repairs

Orthopædic operations numbered 194, including 6 major operations on the hip and 3 on the spine

There were 44 *ophthalmic* and 9 *dental* operations

Radiographic Findings

Of the 1000 cases radiographed 116 films were reported on as abnormal and 29 operations were postponed

Congenital abnormalities 9 cases Only 1 case was of importance, a large pulmonary conus in a child This case was referred to a cardiological clinic, but no definite diagnosis was made

Thickened pleura and diaphragmatic adhesions 14 cases

Emphysema 7 cases One of these showed a localised emphysematous bullæ

se of, and/or infection in, lung 19 cases 8 of in children and 11 in adults 6 cases were l to be minor, and the operation was eventually arranged Of the 13 major infections or collapses 3 were in cases of carcinoma needing immediate treatment They were given intensive preoperative and postoperative physiotherapy and were operated on under an antibiotic screen, one of them under local anæsthesia. 2 cases were already in the hands of the chest physician, and the operations proposed were part of their treatment. 4 cases had severe collapse and infection, thought possibly to be due to bronchiectasis and were referred 2 to the pædiatric physician and 2 to the chest physician. and the operations were cancelled 1 further pat refused treatment and discharged himself from hospital In the remaining 3 cases, early in the se reports were received too late and the operation d without preliminary treatment These 3 patie developed postoperative respiratory complications responded to treatment, 1 of them needing bronchosc before a lower lobe re expanded

Tuberculosis 35 patients were reported as hav healed calcified primary complexes, or calcified foci w no evidence of recent disease, or calcified hilar glan One of these was a child aged 7 years with a report "calcified lesions at right apex, probably tuberculous she was referred to the pædiatric physician for investi tion, the operation being postponed until this had b done 7 adults were reported to have pulmonary tub culosis One of these was already known , the 6 n cases were referred to the chest physician for treatme

Cardiovascular disease 19 cases of cardiac enlar ment or of hypertensive cardiac configuration w reported Only 1 of these patients had symptoms a was referred to a physician before the operation was do 5 patients had not only cardiac enlargement but a hilar congestion 4 of these had already been no clinically as being in heart failure, but 1 patient had n These were all referred to the physician, and their fi outcome was as follows 2 were operated on successfu under local anæsthesia , 2 were operated on un general anæsthesia, and 1 of these, who had a leg amp tated for diabetic gangrene, died on the tenth po operative day , and the fifth patient was not operated

Bone metastases in one film a dense opacity in t 4th rib was reported as being possibly a seconda deposit Since the proposed operation was prostate tomy, the pelvis and spine were radiographed, a carcinoma of the prostate was diagnosed

Comment

From this analysis of 100 preoperative chest radi graphs it can be seen that 29 patients had their operatio postponed or cancelled because of disease first found b radiography The discovery of 6 cases of new ad pulmonary tuberculosis alone justifies the taking of the films

The number of abnormal reports correspond reasonab to the figures given by Wachowski (1954), whose se consisted of all admissions to a general hospital America , and he found rather more rarities. Th proportion of new cases of tuberculosis is higher than th found in mass miniature radiography of the genera public (Stalker 1954)

It is a great comfort to the anæsthetist to know th the patient has had his chest radiographed , if a abnormality is found, one can get advice or treat i accordingly *All 3 patients with preoperative pulmona infection notified too late developed severe postoperati pulmonary complications*

I wish to thank the doctors, nurses, and radiographers a this hospital for their help in instituting and continuing th routine , Dr C W Horncastle, consultant radiologist, witho whose help it would have been impossible , and Mr D W Bracey, consultant surgeon, for help in preparing this pap

RESPIRATORY OBSTRUCTION IN ACUTE LEUKÆMIA

V B LEVISON
M B Lond F.F R D.M R T

SENIOR REGISTRAR, RADIOTHERAPY DEPARTMENT
ADDENBROOKE'S HOSPITAL, CAMBRIDGE

RESPIRATORY obstruction is a rare manifestation of acute leukæmia though in chronic lymphatic leukæmia it is relatively common

Barnick (1898) reviewed the early literature dealing with involvement of the larynx and trachea in leukæmia

Goedel (1932) saw a case of acute myeloid leukæmia in which there were massive œdema of the aryepiglottic region and a hæmorrhagic mass in the glottis, and necropsy showed a hæmorrhagic deposit over the whole inner wall of the trachea extending into the main bronchi

Polisso et al. (1953) described a case of monocytic leukæmia in which laryngeal infiltration necessitated an emergency tracheotomy

A case of monocytic leukæmia was seen by Marks (1953) in which a necrotic membrane involved the left tonsil the vocal cords, and the trachea

Israëls (1953) described an interesting case of reticulum-cell reticulosis of leukæmic form in a woman aged 38 her total white-cell count was 2000 per c.mm. and examination of the bone marrow showed large numbers of the same cells A tracheotomy had to be done because a subglottic mass, presumably composed of the same cells, had almost obliterated the trachea.

I report here two cases of acute leukæmia presenting as respiratory obstruction

Case reports

Case 1—A Polish housewife aged 25 was admitted to hospital on April 26 1954 with six days history of dyspnœa and swelling of the face

On examination she was cyanosed and very distressed by dyspnœa, and superior mediastinal obstruction was present with much œdema of the face and neck. Radiography showed an enormous mass of mediastinal glands presumably pressing on the trachea and main bronchi (fig 1) The total white cell count was 16 000 per c.mm (immature cells 0·5%) but the sternal marrow showed acute leukæmia.

Treatment and Progress—Emergency deep X ray therapy was given to the mediastinal glands two opposing fields 20 × 15 cm (half value layer 1 5 mm. Cu.) being used and a dose of 380r was given to the mediastinum in eight treatments spread over nine days Immediate relief of symptoms followed the first treatment and by May 7 when the treatment was completed the patient was breathing normally and the œdema of the face and neck had gone Her total white-cell count was then 6000 per c.mm (immature cells 28 5%) Re-examination of the chest showed complete resolution of the mediastinal mass (fig 2) No further pulmonary symptoms developed The patient was discharged home but had to be readmitted on May 20 with bleeding from the gums and melæna her total white-cell count then was 22 000 per c.mm (immature cells 68%) She was treated with 6 mercaptopurine and cortisone but did not improve and died on June 4 1954

Case 2—A salesman aged 33 first noticed dyspnœa while cycling in August 1954 and said he felt "his breath was sticking in his throat. Soon after this he had spasmodic swelling of the face and neck and cyanosis. He was admitted to hospital unconscious on Oct 29 1954

Fig 3—Case 2: tomogram showing narrowing of trachea from above clavicles to an inch above carina.

On examination he was breathing stertorously and there were signs of obstruction of the superior vena cava with gross œdema of the face and neck and congested neck veins He regained consciousness after four hours having been given oxygen Radiography of the chest showed in the superior mediastinum a large mass compressing the trachea just above its bifurcation and tomography showed considerable narrowing of the trachea from above the clavicles to one inch above the carina (fig 3) The total white-cell count was 110 000 per c.mm (blast cells 82 5%) The diagnosis of acute leukæmia probably lymphatic was confirmed by examination of the sternal marrow

Treatment and Progress—Emergency X ray therapy was given to the superior mediastinum and trachea two opposing fields 15 × 15 cm. (half value layer 1 5 mm. Cu) being used and a total central dose of 200r was given in three treatments spread over five days. Immediate relief of the respiratory obstruction followed with disappearance of the symptoms of obstruction of the superior vena cava Re-examination of the chest showed considerable diminution of the mediastinal

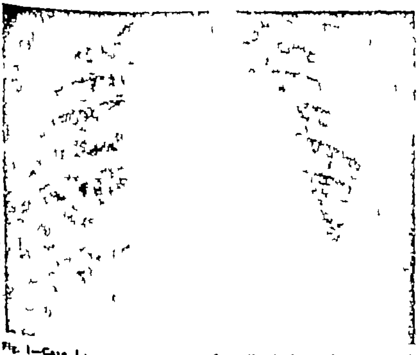

Fig. 1—Case 1: enormous mass of mediastinal glands presumably pressing on trachea and main bronchi.

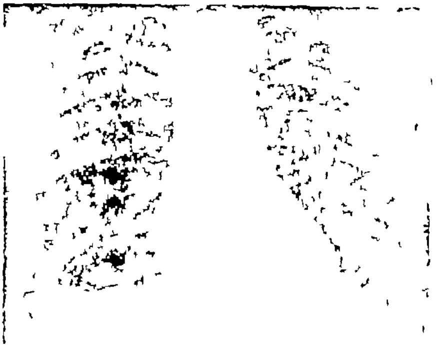

Fig 2—Case 1: complete resolution of mediastinal glands after radiotherapy

glands, disappearance of the mass in the trachea, and establishment of a normal airway The patient has not developed any further symptoms of respiratory obstruction. He is being treated with 6 mercapto purine, and his general condition and blood count are satisfactory

Discussion

In the initial stages of acute leukæmia the lymph glands are not always palpable, though in the later stages of acute lymphatic leukæmia they may be obviously enlarged The condition in which there are an infiltrating lymphosarcoma and a leukæmic blood picture may be termed leucosarcoma, and the two cases reported here come into this category

Sternberg (1915) first described leucosarcoma and considered that it differed from leukæmia and from lymphosarcoma, but this view is not held now (Whitby and Britton 1953) In a series of cases of acute leukæmia reported by Hrodek (1953) only 10% were characterised by swellings, in this group were seen cases showing swelling of the mediastinum, tumour like infiltration of the skin, and multiple infiltrations of various organs It is of considerable importance to distinguish, by examination of the blood and sternal marrow, between cases of leucosarcoma and of lymphosarcoma involving only one group of lymph glands, because the prognosis in leucosarcoma is hopeless, whereas in lymphosarcoma the five-year survival rate is 50% (Boden 1951)

Acute respiratory obstruction due to malignant disease, most often carcinoma of the bronchus, is one of the few radiotherapeutic emergencies Immediate treatment, though not curative, will usually give instant relief from imminent suffocation and death It is generally accepted that radiotherapy is contra-indicated in acute leukæmia (Whitby and Britton 1953, Paterson 1953), but in leucosarcoma presenting with acute respiratory obstruction radiotherapy seems to be of considerable value and may relieve the obstruction and make tracheotomy unnecessary in cases involving the larynx, such as those reported by Poinso et al (1953) and Israels (1953) Leucosarcoma is an extremely radiosensitive tumour, and only very small doses of X rays must be used The response to radiotherapy is very rapid, and the treatment must be given with much care and stopped as soon as the symptoms have been relieved

Summary

Two cases of acute leukæmia presenting as respiratory obstruction are described

In each case complete and permanent relief of the obstruction followed small doses of X rays

The importance of distinguishing between unifocal lymphosarcoma and leucosarcoma is emphasised

Radiotherapy is usually completely contra-indicated in acute leukæmia, but it will relieve respiratory obstruction in this disease, it must be given with the greatest caution

I should like to thank Prof J S Mitchell, F R S, for permission to publish and for helpful criticism, Sir Lionel Whitby, Dr L C Martin, and Dr A. P Dick for permission to publish, Dr F R Berridge for the radiographs, and Miss Sylvia Westoby for printing them

INTRA-ARTERIAL TRANSFUSION IN DIABETIC COMA

R M Kalbag
B Sc, M B Bombay
SENIOR HOUSE OFFICER, DEPARTMENT OF NEUROLOGY, FRENCHAY HOSPITAL, BRISTOL

J M Naish
M A, M D Camb, F R C P
CONSULTANT PHYSICIAN, BRISTOL CLINICAL AREA

Surgeons used to dealing with severe states of shock following massive hæmorrhage and tissue damage have quickly come to realise the value of intra arterial transfusion in resuscitating the nearly moribund patient whose systolic blood-pressure has dropped below 70 mm, Hg Because intravenous transfusion of blood has little effect in restoring a normal circulation in such cases, the term irreversible shock has often been used in the past

Intra-arterial transfusion has also been used with success for severe shock in medical conditions, such as cardiac infarction and various types of embolism. We record a case of diabetic coma in which peripheral circulatory failure had reached a stage which would in the past have been considered irreversible, and in which an intra arterial transfusion of two pints of blood was the turning point towards eventual recovery

Case-report

A woman, aged 63, not previously known to be diabetic, who had complained of anorexia and constipation for two months, began to vomit profusely thirty six hours before admission She became drowsy and finally comatose twelve hours before admission

On examination she was obese but extremely dehydrated, with respirations deep and hungry, extremities cold temperature 97°F, and blood pressure 80/60 mm. Hg Her urine contained glucose and acetone Her blood sugar level was 463 mg per 100 ml, and bicarbonate 19 5 vol %

Treatment and Progress —She was given 25 units of soluble insulin intravenously and 75 units intramuscularly, and intravenous therapy was started with physiological saline solution 400 ml A blackish foul gastric residue was aspirated. After two hours the blood sugar level had risen to 800 mg per 100 ml and the blood pressure had fallen to 50/25 mm. Hg Insulin 160 units was given, and intravenous dextran was substituted for the saline solution Venous spasm, persisting after the injection of procaine, prevented very rapid transfusion, and signs of pulmonary œdema began to appear five hours after the start of treatment At this time the blood sugar level was 650 mg per 100 ml and the blood-pressure 55/40 mm Hg The patient was cold and livid, her breathing was stertorous, and the end seemed imminent. A pint of blood was then transfused into the right radial artery in ten minutes, the general condition improved, and the blood pressure rose to 100/65 mm Hg A further pint was then given in five minutes, with a further improvement in general condition An hour after the beginning of intra arterial transfusion the blood pressure was 115/75 mm Hg and the patient's extremities were warm Intravenous therapy was continued through a polyethylene catheter in the left saphenous vein, 2 litres of 1/6 *M*/sodium lactate and ¾ litre of physiological saline solution being given in four hours Insulin 60 units was given at hour eight, and at hour ten the blood sugar level was 246 mg per 100 ml Thenceforward treatment was continued with sodium lactate, physiological saline solution, and potassium chloride intravenously according to the estimated needs, and insulin was given four hourly After twenty four hours the patient was just able to swallow fluids, and, although for two more days her condition was critical and recovery was complicated by sepsis at the sites of the intravenous and intra arterial transfusions by urinary infection, and by a recurrence of iritis in one eye, she has eventually been stabilised on 70 units of insulin zinc suspension ('Lente')

Comments

In the experience of one of us, such a degree of peripheral circulatory failure in diabetic coma always presages death, and accelerating the rate of intravenous infusion, even if that is possible, seems to precipitate pulmonary œdema Intra arterial transfusion although an unusual method of treatment seemed to offer the only hope of halting the cycle of events leading to circulatory failure and death

The transfusion was effected with a Hamilton Bailey cannula tied into the radial artery just above the wrist and connected to a form of pressurised-saline outfit on a stand which has been in regular use in Frenchay Hospital Bristol since 1948 mainly for angiography principally carotid (Mortimer and Gaskell 1954) Alternative routes, perhaps preferable from the point of view of maintenance of continuity of the artery would be either percutaneous introduction of a 6 in B W G no 17 needle into the femoral artery or direct puncture of the brachial artery at the elbow after exposure The use of a Macintosh and Pask safety drip chamber excludes the possibility of air-embolism but the blood has to be prefiltered, no filter being provided with the apparatus

NORTH LONSDALE HOSPITAL BARROW IN FURNESS LANCS

Since Kussmaul and Maier (1866) first described periarteritis nodosa this term has been used to describe various conditions the common factor being a generalised arteritis or angiitis varying in type and distribution

Numerous cases of periarteritis have been attributed to sensitisation to drugs—e.g sulphonamide (Rich 1942, More et al 1946) sulphathiazole (Lichtenstein and Fox 1946) thiouracil (McCormick 1950) thiourea (Gibson and Quinlan 1945), penicillin (Surdakowski 1951 Adelson 1951) organic arsenicals (Miller and Nelson 1945), dilantin aspirin and Lugol's iodine (Rich 1947); and the resulting lesions which differ in some respects from those of classical periarteritis nodosa have been called hypersensitivity angiitis (Zeek 1952 Knowles et al 1953) We have not been able to trace any reference to hypersensitivity angiitis following the administration of streptomycin or of isoniazid

Another important group of cases of periarteritis nodosa is often associated with hypertension and renal impairment and has been called microscopic periarteritis nodosa (Davson et al. 1948, Wainwright and Davson 1950)

Additional descriptive terms used for members of this group of diseases include polyvasculitis (More et al. 1946) primary and secondary periarteritis nodosa allergic granulomatous angiitis, rheumatic arteritis temporal arteritis (Zeek 1953) polyarteritis nodosa and necrotising arteriolitis (*Lancet* 1954)

The importance of a better understanding of these diseases has recently been emphasised (*Lancet* 1954), particularly because a possible means of treatment is now available in corticotrophin and cortisone The present case is reported as an example of hypersensitivity angiitis in which death occurred suddenly during treatment with cortisone

Case report

Mrs A a housewife was treated in 1951 at the age of 30 for a sterile mammary abscess which *settled completely* a few days after incision a chest radiograph at that time was normal

She remain well until April 1954 when she developed suppurative otitis media which was treated with systemic penicillin This had to be discontinued after a few days because of fever and a general rash shortly after this she developed right sided pleuritic pain which persisted On May 20 1954 radiography of the chest showed two dense homogeneous rounded opacities in the lower zone of the right lung one 2 cm in diameter lying at the anterior end of the greater fissure and the other (6 cm. in diameter) lying posteriorly in the costophrenic sulcus (fig 1)

She was first seen by one of us on June 24 when the right pleuritic pain had been worse for the past few days. She was found to have a small right pleural effusion and she was admitted to hospital the same day The effusion was clear and contained lymphocytes, but no tubercle bacilli were found on direct examination or culture The diagnoses considered at that time included secondary carcinoma tuberculomata pyæmic abscesses, and infarcts. In the absence of any evidence of a primary carcinoma a course of anti tuberculosis chemotherapy was started the intention being to proceed to thoracotomy if the diagnosis remained in doubt The effusion cleared in two weeks leaving the diaphragm considerably raised and subsequently the rounded lesions were not radiologically visible

Course of Illness

Treatment with streptomycin 1 g daily and isoniazid 200 mg daily was started on June 28 On July 4 she had fever (102°F) and a general maculopapular rash, which she said was exactly like what she had had after treatment with penicillin. The pyrexia increased and on July 6 streptomycin therapy was discontinued and full doses of promethazine (Phenergan) were given Isoniazid therapy was not discontinued until July 8 The *pyrexia which had remained at* 104–105 F until July 8 gradually settled to about 100°F; at this time there was eosinophilia (594 per c.mm.) which was not maintained

By July 10 the rash had largely cleared but on the 14th she developed acute retention of urine requiring an indwelling catheter; at the same time all the tendon jerks were brisk those in the right leg being much increased The plantar responses were flexor and the abdominal reflexes present; there were no sensory changes. Her general condition remained poor drowsiness being a striking feature; the *skin of the* legs had started to desquamate The blood pressure was 115/70 mm. Hg and blood urea level 22 mg per 100 ml

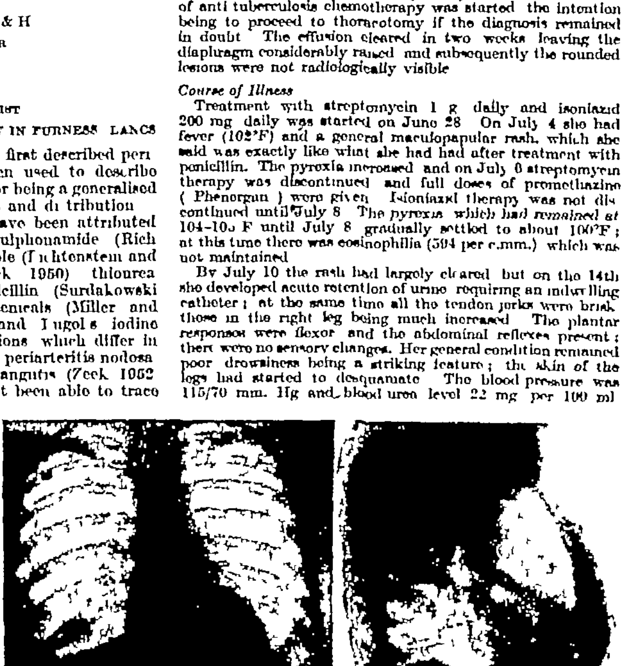

Fig 1—May 29 1954: two dense homogeneous rounded opacities in lower zone of *right lung* one lying at anterior end of greater fissure and the other posteriorly in costophrenic sulcus.

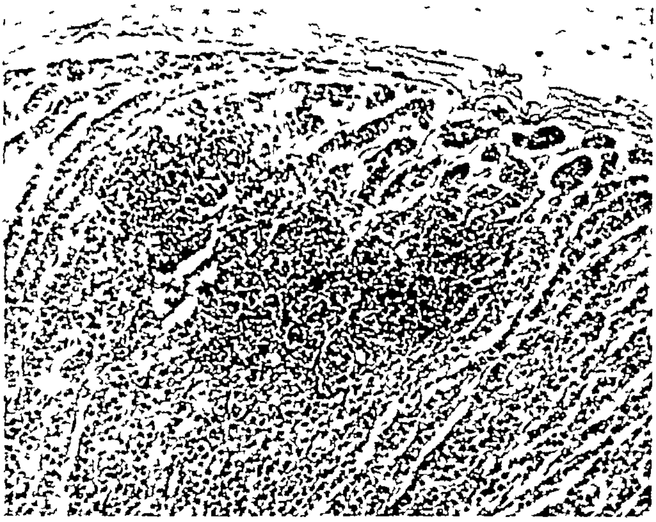

Fig 2—Necrotic area in suprarenal cortex (× 77¹/₂)

The right fundus oculi was normal, but there were two well defined patches of exudate on the nasal side of the left disc, there was one perivascular exudate on the temporal side of the disc but no hæmorrhage or papillœdema

On the evening of July 14 she had signs of a pulmonary embolism in the left lower lobe, apparently arising from thrombophlebitis in the left calf Anticoagulant treatment with heparin and phenylindanedione ('Dindevan') was started but had to be stopped after twenty four hours because of gross hæmaturia

All drugs were now discontinued, and the patient gradually improved Extreme drowsiness remained the chief feature of the clinical picture By July 26 the neurological signs had completely regressed, and micturition was normal, but slight desquamation was now general

On Aug 10 a test dose of intramuscular streptomycin 0 1 g was followed by mild evening pyrexia (99 2°F) and next day by aching finger joints and back for a few hours On Aug 13 a test dose of isoniazid 20 mg was followed by evening pyrexia (100°F) and next day by severe bilateral conjunctivitis, and the pyrexia subsequently gradually increased to 102 4°F The eye condition progressed and presented a picture indistinguishable from phlyctenular conjunctivitis due to sensitivity to tuberculo protein, a Mantoux test, with 1/1000 O T was negative Drowsiness increased, and the patient complained of stiffness in all her joints

Treatment with Corticotrophin

Polyarteritis being suspected, treatment with corticotrophin 100 mg daily was started on Aug 19 The following day the temperature returned to normal, and the eyes, though still injected, were very much improved The dosage of corticotrophin was reduced after two days to 75 mg daily, and after another two days to 50 mg daily On Aug 23 the patient's condition again deteriorated with pyrexia (101°F) and a relapse of the eye signs Next day treatment with cortisone acetate 25 mg six hourly by mouth was started and continued until Aug 30, no corticotrophin being available During this period she was maintained on a low salt diet and her intake of fluids was restricted to two pints daily

On Aug 29 she complained of breathlessness and retrosternal tightness, and on auscultation there were abundant râles throughout both lungs On the 30th the blood-urea level was 300 mg per 100 ml, compared with 22 mg two weeks previously The blood pressure was 120/80 Electrocardiography showed no abnormality other than prominent T waves, presumed to be associated with the uræmia Radiography of the chest showed diffuse shadowing in keeping with pulmonary œdema The symptoms became worse, and the patient produced copious pink frothy sputum She died on Aug 31

Necropsy Findings (Sept 1)

External examination showed an operation scar below the right breast and some exfoliation of the skin of both legs. A little free fluid was found in the left pleural cavity Both lungs had firm dark red areas at the bases with overlying fibrinous pleurisy, the rest of the lungs being œdematous. The myocardium was pale, otherwise no cardiac abnormality was found The kidneys were swollen and had pale mottled cortex The spleen was moderately enlarged, firm, and pale at the surface, with perisplenitis The liver was somewhat pale The other organs appeared normal to the naked eye.

Histological Examination

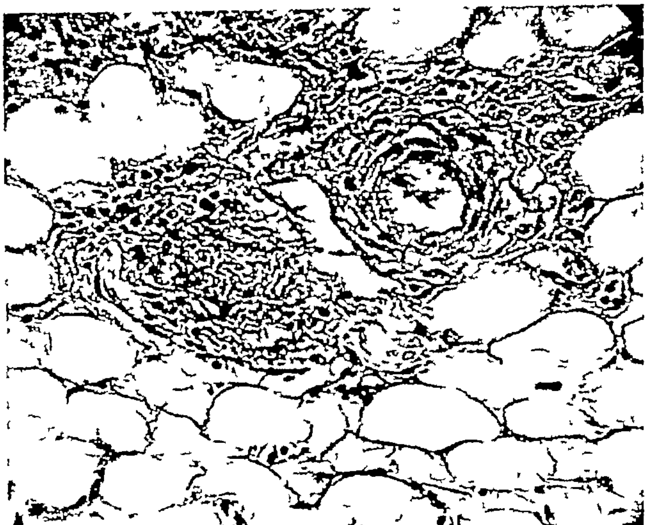
Kidneys —Widespread fibrinoid necrosis of the glomerular tufts, with polymorph infiltration around the capsule. Many tubules contained hyaline and leucocytic casts and red blood cells The interstitial tissue showed round cell and polymorph infiltration No evidence of arteritis was seen in any of the larger vessels examined

Lungs —There were numerous areas in which the alveoli contained fibrin, red cells, and polymorphs, the arteries in these areas being involved by polyarteritis There was no evidence of tuberculosis or of pulmonary sepsis

Suprarenals —Small areas of necrosis in the cortex of both glands (fig 2), no involved vessels were seen in the gland substance, but several were affected in the surrounding fat including a small vein (fig 3)

Small arteries in the *heart* (fig 4), *spleen*, and *portal tr* were affected

The lesions corresponded in nature and distribut to those described by Zeek (1952) as hypersensitiv angiitis, and, except for the involvement of a sm



ected arteriole and vein in perinephric fat (× 244)

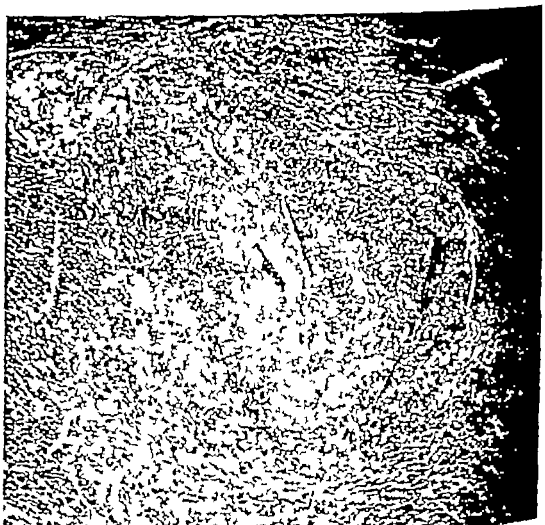


Fig 4—Affected coronary artery (× 25)

tein to those described by Davson et al (1948) as microscopic periarteritis nodosa

Discussion

We now believe that the round opacities seen in the right lower zone of the chest radiograph in April 1954, were due to infarcts and postulate that arteritis had already developed probably as a result of sensitisation to penicillin in March 1954 Subsequently this condition appears to have been aggravated by the exhibition of other antigens in the form of streptomycin and isoniazid after a tentative but mistaken diagnosis of tuberculosis It was not until the patient had recovered from the more usual effects of sensitisation to these drugs (pyrexia, exfoliative dermatitis, and hyperreflexia) and developed a progressive and obscure illness following exhibition of single small test doses that a collagen disease was suspected.

She was then treated with corticotrophin and later cortisone but after two weeks, during which her clinical condition improved somewhat she developed acute fatal cardiorenal failure At no time was the blood pressure raised

Zeek (1952) suggests that, since periarteritis nodosa and malignant hypertension have been produced in rats by the administration of either adrenal or pituitary hormones it may be dangerous to use cortisone or corticotrophin in cases with certain types of necrotising vascular lesions. Rich et al (1950) in experimental work on rabbits in which periarteritis nodosa and glomerulonephritis were induced by sensitising them to horse-serum found that whereas corticotrophin prevented the development of the renal lesions cortisone, in contrast, induced a severe hæmorrhagic type of glomerulonephritis which was distinct from the proliferative variety resulting from sensitisation

More recently several workers have described instances where periarteritis nodosa was possibly caused by treatment with these hormones

Levin et al. (1953) reviewing 50 patients with rheumatoid arthritis treated with cortisone and corticotrophin mention 3 who developed histologically proved periarteritis nodosa (1 during treatment and 2 shortly after treatment with the hormones was withdrawn) They point out that other collagen disorders may coexist with rheumatoid arthritis (Bauer et al. 1952)

Robinson et al (1953) describe 4 patients with rheumatoid arthritis who developed diffuse arteritis, of whom 3 had been treated with corticotrophin and 1 had not.

A similar case of polyarteritis nodosa developing during cortisone treatment of rheumatoid arthritis is described by West and Newns (1953)

Corticotrophin has been incriminated as the cause of serious or fatal allergic reactions

H. T Howat cited by Savidge and Brockbank (1954) and Hill and Swinburn (1954) each report a fatality following injection of corticotrophin due to anaphylaxis

Nabarro (1954) remarks on the danger of allergic reactions to corticotrophin particularly where the adrenal glands fail to respond and the level of circulating steroid hormones is low

Stoner and Whiteley (1951) found that the adrenals of 4 patients who died under treatment with corticotrophin were hypertrophied whereas those of 3 patients who died under treatment with cortisone were atrophied and inactive Whereas the diseases being treated with corticotrophin were sufficient to account for death, those being treated with cortisone were not The adrenals of the present patient who received both hormones for only short periods showed numerous small areas of necrosis

We offer no explanation for the course of events in the case we describe but we believe that the possibility that the patient became sensitised in turn to the hormones, with further aggravation of the generalised angiitis cannot entirely be ruled out The experimental work of Rich and his associates suggests that in the present state of knowledge patients with any form of polyarteritis should be treated with corticotrophin rather than cortisone in view of the possible nephrotoxic action of the latter hormone

Summary

A case is described in which generalised hypersensitivity angiitis developed evidently as the result of sensitisation to penicillin streptomycin and isoniazid

Death took place suddenly from acute cardiorenal failure during treatment with cortisone

Our thanks are due to Mr H. C Taylor for the photomicrographs

CONGENITAL DIAPHRAGMATIC HERNIA
IN A PREMATURE INFANT

C L. Clinton Thomas
F.R C.S
SURGICAL SPECIALIST MALAYAN MEDICAL SERVICE

Early diagnosis and immediate surgical intervention are largely responsible for the progressive decline in the mortality from congenital defects of the diaphragm. At one time surgical opinion favoured postponing the operation until the child was 1 or 2 years old but Hedblom (1925) showed that three quarters of these infants died before the end of the first month

In the last decade it has been established that during the first 48 hours of their life infants can withstand major surgical procedures which they will *not* tolerate later The early operation has the added advantage that, during the first 2 days of life, the intestines are not yet distended with gas and repositioning is easier This is a serious problem in congenital diaphragmatic hernia because the capacity of the abdominal cavity is considerably reduced

In infants who are operated on after the first 2 days replacement of the viscera and closure of the abdominal wall if possible at all gives rise to serious cardiorespiratory embarrassment which often proves fatal Ladd and Gross (1940) were the first to advocate a two stage closure of the abdominal wall in certain cases and this proved an important advance in treatment

Other important causes of the progressive decline in mortality have been the segregation of these cases in pædiatric and thoracic surgical centres improved techniques in anæsthesia, and the better understanding of preoperative and postoperative treatment in neonatals.

Several large series have now been reported including those by Hartzell (1940) Harrington (1948) Gross

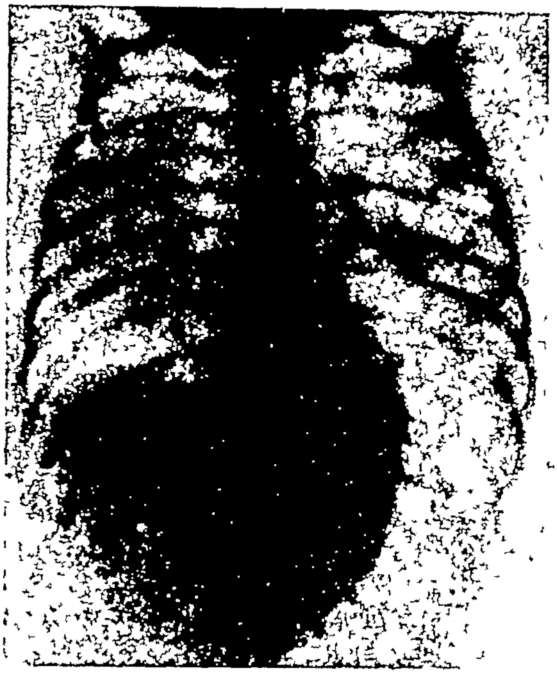

Fig 1—Radiograph of chest before operation

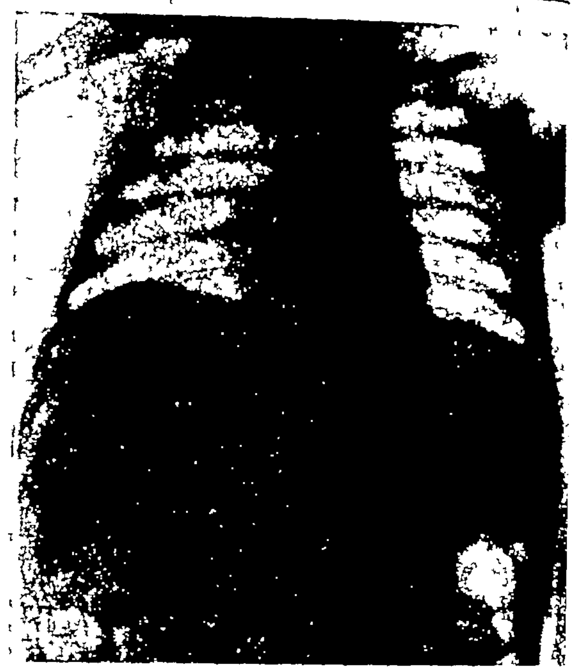

Fig 2—Radiograph after operation

(1953), and Ricker (1954) My justification for recording a single case only is that it shows that success is possible in a poor-risk subject, in the absence of modern anæsthesia and specialised nursing This may encourage surgeons who work in parts of the world where such important aids to surgery are not available

Case-report

A premature male Indian infant, who weighed 4 lb 8 oz at operation, was noticed to be cyanosed on the third post natal day The cyanosis progressively increased, and the infant began to have attacks of respiratory embarrassment and vomiting during feeding Despite these ominous signs a careful examination was not made, and penicillin was given empirically for what was thought to be a respiratory infection Though there was no improvement in his condition, the chest was not radiographed till the twelfth day The film revealed a diaphragmatic hernia with many loops of gas filled intestine filling the left hemithorax (fig, 1) The infant was accordingly referred for surgical treatment

On admission he was cyanosed, dyspnœic, and dehydrated The apex beat was in the right anterior axillary line, and the abdomen was scaphoid.

Dehydration was corrected with subcutaneous half normal saline given through a drip with the aid of hyaluronidase, and gastric suction was begun

Operation

After a left phrenic crush, the abdomen was opened through a left paramedian incision extending from the costal margin to below the umbilicus Anæsthesia consisted in local infiltration of the line of the incision with 1% procaine and adrenaline 1 in 500,000, very small amounts of ether were given, using an open mask, with oxygen supplied through an intranasal catheter

The hernia was through the patent left pleuroperitoneal canal—the so called foramen of Bochdalek The hernial contents were gently reduced after air had been admitted to the pleural cavity through a soft rubber catheter As is usual in this type of hernia, there was no sac

The organs which had herniated were the left lobe of the liver, the stomach and first part of the duodenum, the jejunum, the ileum, the cæcum, ascending colon, transverse colon, the tail and body of the pancreas, and the spleen It was at once apparent that it would be impossible to replace all these viscera in the underdeveloped abdomen A two stage reduction was therefore decided upon

The hernial orifice was repaired in two layers with mattress of fine braided nylon, without preliminary paring phragmatic edges As the last suture was being tied, air was evacuated from the pleural cavity through a fine catheter attached to an abdominal sucker

The skin and subcutaneous tissues at the sides of the abdominal incision were widely undermined As much of the bowel as possible was returned to the abdomen, and the rest was left under the sutured skin as a ventral hernia

Postoperative Progress

At the end of the operation the infant's condition was fairly satisfactory He was placed in an incubator and remained there for 5 days Gastric suction and subcutaneous fluids were continued for 24 hours, when feeding with expressed breast milk was begun. Penicillin 100,000 units twice daily and ascorbic acid 250 mg daily were given postoperatively

As the infant's condition remained completely satisfactory and a radiograph of the chest showed full expansion of the left lung (fig 2), it was decided to repair the ventral hernia on the 7th day However examination of the abdominal wound on that day showed a moderately severe wound infection, though there was no pyrexia (A swab from the wound subsequently grew a penicillin insensitive *Staphylococcus aureus*) Operation was postponed and the wound treated with 5% chloramphenicol in propylene glycol, while chloramphenicol palmitate (100 mg 8 hourly) was given by mouth

The wound infection had cleared up by the 14th postoperative day, and 2 days later the ventral hernia was repaired and the abdominal wall closed in layers

Recovery from the second operation was uneventful and the wound healed by first intention The infant was discharged from hospital 3 weeks later, by which time he was gaining weight normally Subsequent progress was satisfactory, but when the child was last seen, a year later, radiographic screening showed that the left diaphragm was raised, and paradoxical movement indicated that the paralysis had not recovered.

Comment

Ladd and Gross (1940) originally advised preliminary crushing of the phrenic nerve to decrease tension on the diaphragm caused by suturing the opening Healing takes place satisfactorily without this aid, and Gross (1946) has since abandoned the procedure because—as in this case—the paralysis of the diaphragm is sometimes permanent

Reviews of Books

The Physician and His Practice

Editor JOSEPH GARLAND M D editor *New England Journal of Medicine.* Boston and Toronto Little Brown. 1955 Pp 270 $5 00

IN this 'source book of information regarding his career for the young doctor in the United States, 18 contributors (13 medical, 5 lay-expert) survey the whole field of medical practice—opportunities obligations, rewards, and perils, and give detailed advice on all except clinical matters to the intending general practitioner For the British reader its interest lies in comparison. It seems that fragmentation of medicine has gone further there even than here so that general practice in cities has become something very different from ours. In small towns and the country however the generalist' may fully deserve that title besides having his part to play in vigorous and abounding social and communal life Graduation to special through general practice still occurs, and group practice of various kinds is increasing In one respect the American G P scores heavily: it seems to be recognised that wherever he may practise he must in some way be affiliated to a hospital, "since he will stifle medically without it. "Perhaps Dr Garland comments, a way will be found to modify the present scheme in Britain and give the general practitioners some access to hospitals. It would seem a safe assumption that if this is not done the caliber of general practice is likely to deteriorate in time.

Hey Groves's Synopsis of Surgery

Editor SIR CECIL WAKELEY BT K.B.E C.B LL.D., F.R.C.S senior surgeon King's College Hospital, London. Bristol: John Wright & Sons. 1954 Pp 660 30s

THERE is a great deal to be said for this synopsis, and when an ordinary treatise of surgery has been read and re-read. For revision in the last month or so before an examination, and as a companion at outpatient clinics and round the wards it is invaluable Its merit resides in its ultimate degree of terseness a treatment may be summarised in a single word capable of recalling a memory It saves the student from re-reading what he already knows, but forces him back to his textbook for what he has forgotten Students owe a debt of gratitude to Sir Cecil Wakeley for editing this new edition

X ray Atlas and Manual of Esophagus, Stomach and Duodenum

Dr T J J H MEUWISSEN consulting physician and radiologist at Eindhoven, The Netherlands. Amsterdam and New York: Elsevier London: Cleaver Hume 1955 Pp 687 £8 15s

IN the introduction to this work we are told that material for it has been gathered from twenty five years experience in gastro-intestinal radiology Nearly 500 cases are described briefly and are very well illustrated This mass of clinical material would have made the book difficult to read if the author had not adopted the method he has done: after a comparatively short and very practical survey of the anatomical arrangement and diseases in different regions he groups the illustrative cases as a block The illustrations are of course keyed to the text so it is possible to use them as references either independently or in conjunction with the text A short appendix deals with the stomach after operation No attempt has been made to include references to published works. This is a very helpful book and well produced

Management of Endocrine Disorders of Menstruation and Fertility

GEORGEANNA SEEGAR JONES M D assistant professor of gynecology Johns Hopkins University Springfield Ill Charles C Thomas. Oxford Blackwell Scientific Publications. 1954 Pp 108 42

THIS book is written for the medical student and physician be he specialist or practitioner : but it is better suited to be a primer for student endocrinologists The pituitary and gonadotrophic hormones have certainly been called by many different names and are assayed in many different ways by many different workers, but nine-tenths of these early confusions might have been relegated to an appendix, or at least to footnotes. Here and there the clinician will prick up his ears, hoping to learn something to his advantage but the imprint of clinical experience seems to be lacking A discussion on delayed menarche, for instance, gives the impression that imperforate hymen is high on the list of causes. Treatment of the menopause is dismissed in only one short page; the suggestion that stilbœstrol should be given in doses of 1 mg daily is not likely to commend itself to most recipients and the reader, having been advised that œstrogen treatment must be discontinued as rapidly as possible is then told that ' pellet implantation is most satisfactory when feasible '

Psycho chirurgie et fonctions mentales

J LE BEAU Paris Masson 1954 Pp 430 Fr 3300

IN this book Dr Le Beau a neurosurgeon who has worked particularly in the field of psychosurgery reviews the practice of cerebral surgery in mental illness, including intractable painful states.

After a brief section on the anatomy and physiology of the frontal lobes and their related structures in the thalamus, diencephalon and brain-stem, he discusses, mainly in terms of Eysenck's theories of ' neuroticism and psychoticism, the psychological functions involved in the mental diseases treated He goes on to describe his own experience and gives details of the operative techniques he uses and their possible surgical and medical complications The main part of the book is taken up by a review of the indications for the different operations and their clinical results both in mental disease and for the treatment of intractable pain. This section contains a full discussion and assessment of Dr Le Beau's own results in which postoperative psychological changes have been assessed by Mrs. A. Petrie. There are also brief chapters on temporal lobe surgery in conduct disorders and on the placing of selected lesions in the subcortical nuclei of thalamus and basal structures by means of the *stereo-encephalotome.* In a final chapter on physiological interpretations there is perhaps a tendency to assign rather naively symptomatic changes to specific cortical areas and cerebral structures.

In general however this work covers psychosurgery more fully than many earlier books, which have tended to deal largely with one operation, and surgeons will find it a valuable source of reference

Manual of Hand Injuries

H MINOR NICHOLS M D., clinical instructor in surgery University of Oregon Medical School Portland Chicago: Year Book Publishers London: Interscience Publishers. 1955 Pp 352 72s

WELL illustrated and attractively presented this book provides a complete picture of the problems arising in the treatment and care of injuries of the hand—including amputations, burns tendon and muscle injuries nerve injuries, fractures, and dislocations It also deals with infections secondary tendon repairs, and more complicated reconstructive procedures. The text indicates the tendency towards more serious study and care of hand injuries and the trend in the better hospitals to make the casualty department rather more than a reception station It is a treatise that is of the greatest value to surgeons concerned with the treatment of such injuries, and can be strongly recommended

The Origins and History of Consciousness

ERICH NEUMANN Translator: R F C HULL. London: Routledge & Kegan Paul 1954 Pp 493 30s

FROM any reader not familiar with the Jungian modes of thought and language this book demands steady concentration an unlimited capacity to digest abstractions, and a considerable tolerance for ponderous and imprecise argument If he can bring these rare attributes, he will be rewarded by many unusual and stimulating connections that are suggested between the primitive or archetypal phases of the development of consciousness in individuals and the mythological symbols and tales which are projections of the collective unconscious of mankind The work is essentially an esoteric study in individuation; it seeks to relate ontogenesis to phylogenesis As always in Jung's analytical psychology, the apparatus of scholarship is fully deployed, and the writer shows a wide acquaintance with ancient religious and ethnological writings, especially those concerned with the ubiquitous symbol of the Uroboros—"the circular snake, the primal dragon of the beginning that bites its own tail" Cursory exposition of the way Dr Neumann develops his theme is impossible, because of the unconventional line of thought and the range of issues traversed

---

Abdominal Operations (3rd ed London H K Lewis 1955 Pp 1580 £8 10*s*)—Mr Rodney Maingot's work has an established place in British surgical literature, and the third edition has broadened its scope There are now 24 contributors, 8 from overseas, chosen for their expert knowledge in a special subject, and a detached and reasoned approach to each topic is maintained throughout, with ample references The number of illustrations has been increased considerably The revision required for this edition must have been a considerable undertaking, but it has been well worth while

Cold Injury—The Josiah Macy, jun, Foundation, New York, has published the transactions of the conference on this subject held in February, 1954 The editor is Dr V. Irené Ferrer (1955 Pp 226 $4 50)

Technique and Significance of Œstrogen Determinations—The proceedings of a conference on this subject held by the Society for Endocrinology and the endocrinology section of the Royal Society of Medicine in February, 1954 have been published as no 3 of the Memoirs of the Society for Endocrinology The editors are P Eckstein and S Zuckerman Beginning with this number, the Memoirs are being published by the Cambridge University Press, from which copies of Memoirs 1–3 can be obtained (1955 Pp 95 18*s*)

New Inventions

A RULER FOR USE IN ELECTRO-ENCEPHALOGRAPHY AND ELECTROCARDIOGRAPHY

THE measurement of frequency of waves, occurring in short bursts in electro-encephalograms, with a centimetre ruler is tedious and not alleviated by the wave analyser, which analyses epochs of ten seconds To make such measurements easier a ruler has been designed to measure frequency and amplitude of waves The same ruler can also be used for measuring intervals in seconds and cycles per minute so that it is possible to analyse an electrocardiogram displayed on plain paper The ruler is simple to make and does not require the skill of an instrument maker This is important because the dimensions of the ruler are determined by the paper speed of each instrument

The ruler is made by etching lines on a piece of 'Perspex' 8 cm × 12 cm × $^1/_8$ in A triangle is etched whose base is 6 cm (or the distance moved by the paper in 2 sec) and vertical height 10 cm The base is divided into six equal parts, and the divisions are joined to the apex of the triangle From the two lines adjacent to the vertical, horizontal lines are etched towards the edge of the ruler, the ones on the right indicating cycles per second (C P S) and those on the left indicating fractions of a second In etching the scale markings, the distance, in centimetres, from the apex of the triangle (measured along the vertical) to the scale markings is calculated as follows

(1) *C.P.S* Distance =

$$\frac{\text{C.P.S represented by 1/6 base (3)} \times \text{vertical height (10)}}{\text{C P S on scale}} = \frac{30}{\text{C P S on scale}}$$

(2) *Seconds* Distance =

$$\frac{\text{Vertical height (10)} \times \text{seconds on scale}}{\text{Seconds represented by 1/6 base (1/3)}} = 30 \times \text{seconds on scale}$$

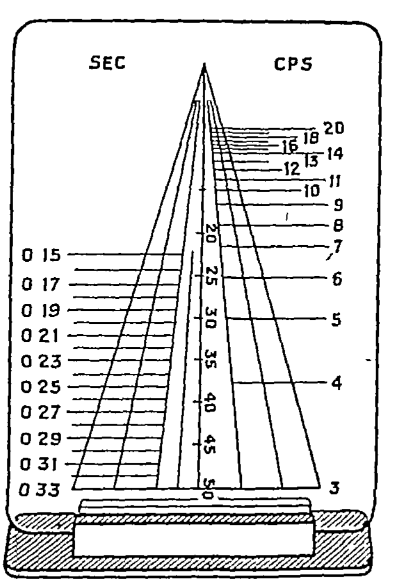
The *vertical line is* marked in centimetre divisions

When the base of a wave is cut by the vertical and the line adjacent on the right, its frequency can be read from the C P S scale on the right Similarly, when the vertical and the line adjacent on the left are used, the duration of the wave or interval can be read on the seconds scale on the left Should lines other than those immediately adjacent to the vertical be used, the figures representing C P S and seconds are doubled or trebled Alterations can also be readily made when the paper speed is halved or doubled

When the sides of the triangle cut similar points in two cardiac cycles in the electrocardiogram, the cardiac rate is read on the C P S scale and the number multiplied by ten This is obvious when it is remembered that the base represents 2 seconds—i e, 30 C P M.

The ruler can be used in such a way that the vertical line of the triangle lies along the base of a series of waves The ruler is then moved to the right or left until one of the lines above the vertical cuts the apex of the wave to be measured The point on the vertical line where this occurs indicates the voltage of the wave depending on the calibration of the instrument (in the present case 1 cm is equivalent to 50 µV)

It is an advantage to etch an additional line midway between the vertical and the line adjacent on the left because this allows intervals of short duration to be measured When this additional line is used, the numbers on the seconds scale are, of course, halved



It is strongly recommended that the ruler when not in use should be supported on a base so that the perspex *is not scratched*

Some tips for the amateur instrument maker are as follows

(1) When the lines are etched with a ruler and needle, the sheet of perspex should be laid on a sheet of carbon paper

(2) An angle poise lamp enables the light to be directed at an angle most convenient for showing up *the lines.*

(3) When the lines are etched they should be rubbed with carbon paper, and the excess wax removed with a cloth. This makes the lines appear black against white paper

(4) Vertical lines raised *outside the* limits of the ruler on the sheet of perspex avoid unnecessary and unsightly marks on the ruler itself

(5) A vibrator tool is useful for etching the numbers. The numbers, of course, must be printed in reverse because the etched surface of the perspex ultimately forms the under surface of the ruler

Voltage markings on the vertical, in multiples of 5 for convenience, can be calculated as follows

Distance, in cm, from the apex to the voltage marking =

$$\frac{\text{(mV or } \mu\text{V on scale marking} \times 30\text{)}}{\text{(Distance moved by paper in 1 sec)} \times \text{(mV or } \mu\text{V equiv to 1 cm)}}$$

Society and the Criminal

> " a crime should never be divorced from the background or setting in which it occurs if it is, then the situation is prejudiced and judgment becomes distorted "

In saying this in the course of his Morison lecture to the Royal College of Physicians of Edinburgh last year[1] Sir **David Henderson** was drawing a close and interesting parallel between the clinical manifestations of nervous and mental illness and the behaviour and thought disorders indicating abnormality and crime

> "They stem he said from the same sources they start early, they are psychobiologically determined are characterised by clinical manifestations which are closely akin, are susceptible to similar methods of investigation and are most successfully treated at a preventive level.

Moreover, as he pointed out in an earlier passage, the responses of society to them are much alike For centuries it was customary to treat brutally patients suffering from acute recoverable forms of mental disorder 'their incurability was manufactured " In a like manner crime has always stirred us to retaliate 'The cry for revenge is hearty and spontaneous ' Insanity still evokes in many people a revulsion not explicable at the conscious level and the aggression evoked by crime has similar obscure origins It is as though these things were infectious breeding in us irrational and antisocial responses which we are not immediately able to recognise for what they are Perhaps it would be truer to say that they rouse uneasy recollections of the same forces in ourselves, forces held perhaps precariously, in check and our automatic defence takes the form of cruelty we would strike down the messenger who brings us evil tidings of our inner selves

The ætiology of criminal behaviour like that of mental illness he believes is complex and cannot be pinned down to a single cause such as environmental stress It must include not only parental attachments but constitutional factors—hereditary developmental endocrine, and metabolic Separation from the mother in the early years may indeed be one such factor but can hardly be the only one in fact criminal behaviour he suggests is not a symptom but a reaction type—a social reaction type if you prefer it but still a psychobiological reaction dependent on our particular make up, however it may have been forged This might seem to hark back to **Lombroso** were it not that Sir **David** allows as much weight to environment as to constitution and has moreover a humane concern for the criminal as a person. He sees him as dominated ("like every other individual) by emotional storms and distorted ideas which may stem from his unconscious life "and which under certain circumstances may be completely uncontrollable" He notes, too, that delinquency, like mental instability, often manifests itself for the first time at puberty and he mentions how closely some older criminals resemble paranoiacs in that starting from wrong premises, they build up a more or less logical argument which is as unshakeable as the systematised delusions of paranoia

Many such people have come under his observation for since 1921 his psychiatric opinion has been sought on criminals whose nervous or mental stability was suspect at trial Before 1932 the cases sent to him were nearly always of murder or attempted murder but since then all manner of behaviour disorders have been referred—cases of theft housebreaking sex offences, fire raising and others He takes this change to indicate a growing alliance between the law and medicine which in time may lead to a better behaved society He classifies 477 cases referred to him under names given of old to three of the seven deadly 'sins lust (*150 cases*), *malice* (*171 cases*), *and greed* (*156* cases) The 150 criminals convicted of crimes of lust ranged in age from 12 to 80 years and came from all walks of life They included 4 cases of bestiality 8 of sodomy 8 of incest, 5 of rape 5 of obscene letter writing 33 of homosexual conduct and 87 of lewd conduct The striking thing about this group as a whole—more astonishing to laymen, however than to doctors—is the high proportion of the criminals who were of normal mentality as assessed by intelligence tests only 12% were diagnosed as insane, 17% as mentally defective and 17% as psychopathic while over half (54%) were 'sane ' in the sense in which the public and the law use the term

> The distribution of the sane (in this sense) in the six subgroups is interesting Thus of the 4 guilty of bestiality none could be classed as sane whereas of the 8 guilty of sodomy all could but that is not to say Sir **David** comments, that they were not strange abnormal individuals who were driven by strong instinctive impulses and desires which became overmastering Of the 8 people guilty of incest, 6 ranked as sane and 1 out of 5 of those guilty of rape could be so classed ; whereas 5 writers of obscene letters were all suffering from paranoid states
>
> All 33 of the homosexuals fell into the sane group Nearly all of them were of high professional standing—schoolmasters clergy Civil Servants, bankers, lawyers and the like Many said they would not change their emotional inversion even if they could but a few were desperately anxious for help

Sir **David** comments regretfully on the inconsistency of the sentences passed on homosexuals which ranged from one to three years imprisonment Where medical treatment seemed likely to be of use the judge often said that whatever medical treatment was needed would be given in prison The effect of imprisonment of course is to confine the homosexual for long periods to the society of his own sex and perhaps to confirm him in his inversion Sir **David** did not make this criticism though doubtless he had it in mind He holds, as do most doctors nowadays that homosexual tendencies most probably depend on a failure to develop and mature the patient remaining fixed at a homosexual level Our aim, he suggests must be to gain the confidence of the legal profession and persuade them to accept this concept This is not easy to do he points out in view of our lack of success in the treatment of homosexuality , but he might perhaps have drawn the analogy of a leg which ceases to grow people neither blame the doctor because he cannot always start the growth process off again, nor abuse the patient for having a limp

---

[1] Society and Criminal Conduct Edinburgh The Royal College of Physicians 1955 Pp 41

> The 87 lewd-conduct cases formed the largest subgroup under the heading of lust, and varied from exhibitionism to interference with young children Only 29 of them were intellectually normal 11 of them were insane, 22 mentally defective, and 26 psychopathic Their oft-repeated offences were often precipitated by alcohol

SIR DAVID remarks on the incurability of these cases, whether treated in a mental hospital or a prison , and on the difficulty of reconciling legal and medical opinion on them Here again we are dealing with a developmental disaster—with people who have reached neither emotional nor instinctual maturity, even though they may " wear the mask of sanity " Sometimes they detest their aberrations as violently as anyone else (as seems to have been the case with the prisoner recently sentenced for assaulting two policewomen [2]) the criminal who is aware of a disorder in himself which society does not recognise as such is not uncommon, and must suffer greatly The 171 crimes of malice included murder, attempted murder, assault, child neglect, threatening letters, and fire raising SIR DAVID found 43% of these criminals insane, and 13% mentally defective or psychopathic (as against only 12% insane and 34% defective or psychopathic among those convicted of crimes of lust)

> Murder is often the solitary crime of a person who otherwise has had a good record, and where there are mitigating circumstances the convicted murderer is often reprieved, and usually makes a satisfactory social adjustment, never committing another offence

The 156 crimes of greed included 122 of theft and 34 of fraud As with crimes of malice, more than half the criminals were insane (33%) or mentally defective (16%) or psychopathic (6%) persons Among those guilty of fraud were some criminals of ability who combined a paranoid personality with an obsessive need to show off , and these, he found, were the most difficult to influence of all criminal types

Abnormality and unsoundness of mind, SIR DAVID HENDERSON argues, cannot be accepted as synonymous , for many criminals are abnormal in that they have failed to fit into ordinary social life, without showing any " unsoundness of mind " which could be certified as such according to existing definitions In this opinion he differs, as he points out, from NORWOOD EAST and HUBERT, who believed that " the normal group of offenders constituted at least 80% of the receptions " He is well aware that the criminals he classes as abnormal, whether sick or not, may be a danger to society, and he recommends that in all cases of serious crime, when the accused's life-history shows evidence of malignant trends, detention should be indeterminate—as it is with certified mental patients Discharge should depend on the attainment of social responsibility This is an extension of the idea of the indeterminate sentence now being tried in Denmark and of the indefinite sentence which is on trial here Finally he urges the great need for more intensive investigation of character traits, so that we may in time be able to distinguish their diagnostic and prognostic significance Forensic psychiatry would then be in a position to point to particular clinical and psychobiological reactions, whether dependent on genes or derived from the environment Such research might also put our profession in a stronger position to convince the lawyers of a concept now generally accepted by doctors—namely, that a person can at one and the same time be intellectually mature and emotionally and instinctually immature that the " sound mind " cannot, in fact, be measured in terms of intellectual performance alone

Valvotomy for Pulmonary Stenosis

THE results of valvotomy for simple pulmonary stenosis are extremely encouraging CAMPBELL and BROCK [1] review 58 cases treated in this way at Guy's Hospital, London 25 of these patients were cyanosed at rest, and a further 7 were thought to become cyanosed with exercise The sex-distribution was almost equal The majority were between the ages of 5 and 29, but 5 were over 30 , and 3 cyanosed children were operated on at 4 years of age Of the 8 deaths associated with the operation 5 were in the first cases , since then there have been 3 deaths in 52 cases Cyanosis betokens increased risk , of the 8 deaths only 1 was of a patient who was not cyanosed As CAMPBELL and BROCK remark, in cases where cyanosis has appeared the best time for operation has been passed The 50 survivors have been followed for or more years (the longest for six) and none has Only 4 patients were not improved In nearly all of the remainder improvement was considerable , for example, a cyanosed woman gave birth to a child eleven months after valvotomy and can now walk as far as she pleases, whereas previously she was limited to a hundred yards In the cyanotic group improved colour and exercise tolerance were observed clinically , but only half of the acyanotic patients showed any disability, and improvement had often to be judged by objective methods alone CAMPBELL [2] suggests that, in the absence of symptoms, the clearest indications for valvotomy are cardiac enlargement, electrocardiographic evidence of right ventricular strain, and a right ventricular pressure of 100 or more mm Hg In the series reported by CAMPBELL and BROCK the heart size, measured radiographically, decreased or remained stationary after operation in nearly all patients with enlarged hearts , but in those with small hearts the size commonly increased a little, apparently owing to their greater physical activity In 3 patients the heart enlarged still further, and in 2 of these the clinical result was poor The electrocardiogram improved in 26 of the 31 cases in which there had been evidence of right ventricular strain Inversion of the T wave in leads V_{1-5} disappeared or decreased considerably , the changes usually began about six months after operation and continued for up to three years The 5 patients in whom the electrocardiograms showed no change included 3 who did not improve clinically, but the remaining 2 have so far done well Cardiac catheterisation was repeated in 24 patients after operation , the right ventricular pressure had fallen to less than half the former figure in all, and to a third in some, and in many the pressure gradient across the valve had diminished remarkably Arterial oxygen saturation was invariably improved in cyanosed patients, in all but 2 the interatrial shunt was abolished and the polycythæmia decreased accordingly

[1] Campbell, M Brock R *Brit Heart J* 1955, 17, 229

[2] Campbell M *Ibid* 1954, 16 273

This series is the largest yet described in detail **Hosier** et al,[3] whose results seem very similar have reported 89 cases in summary **Blount** et al[4] have described a small series of 15, in 5 of which valvotomy was done through the pulmonary artery under hypothermia In these 5 patients the right ventricular pressure was reduced to normal, but pulmonary regurgitation developed in at least 4 This has always been feared as a hazard of pulmonary valvotomy but it was observed only 3 times by **Campbell** and **Brock** and in only 1 patient was it serious While it may seem disappointing that after operation the right ventricular pressure does not fall to normal **Campbell** and **Brock** feel that it is preferable for the surgeon to leave behind mild stenosis than to produce severe regurgitation by attempting too much So far no patient with a good result has begun to deteriorate again, but only further observation will show how long the improvement lasts The operative risk is not large and the mortality is likely to be reduced by submitting patients to valvotomy as soon as the need becomes apparent

Annotations

ULCER-CANCER OF THE STOMACH

In his Macewen lecture Prof Matthew Stewart has once more raised the topic of ulcer-cancer in the stomach[5] Examination of 1510 specimens removed surgically showed a combination of chronic simple ulcer with carcinoma in 103 and coexistence of the two lesions in a further 13 Simple ulcer was present in 935 cases. This might suggest that the proportion of simple ulcers which become cancerous is about 10% but as Stewart observes many gastric ulcers heal spontaneously so in fact the ratio must be lower For other reasons too it is difficult to assess the incidence of ulcer cancer Gastric carcinoma is more commonly situated in the pyloric region than on the lesser curve in the ratio of about 3 to 1 whereas for simple gastric ulcer the ratio is reversed Since patients with a simple prepyloric ulcer are liable to come to *operation* earlier owing to earlier complications than those with a similar lesion on the lesser curve the material from surgical specimens can hardly be regarded as a random sample Similarly with cancer pyloric lesions are diagnosed earlier and operated on earlier the fact that cancer of the body is more often removable and is therefore more likely to provide specimens adds a bias in the opposite direction but it is unlikely that these two considerations neutralise one another

Beattie and Moroney[6] approached the problem statistically in an attempt to prove that in the stomach an association between simple ulceration and cancer does exist but because of errors of sampling in existing evidence they were unable to do so Ivy,[7] approaching the problem experimentally, has examined the possible action on gastric mucosa of carcinogens—overheated fats certain food dyes and methylcholanthrene He concludes that water-soluble agents may incite malignant change directly but those insoluble in water can produce malignant degeneration only in the presence of a chronic ulcer or gastritis since secretion of mucus and epithelial desquamation protect the mucosa adequately This work indicates possible explanations of ulcer-cancer but provides no proof.

STANDARDISATION OF WOUND TEXTILES

Most wound dressings are applied to protect the injured surface from contamination and to absorb exudate For these purposes gauze and if the secretions are copious cotton wool are commonly used Baron[1] has compared in laboratory animals the mortality and the rate of wound healing with different dressings Where the wound was superficial, healing was more rapid if the raw surface was exposed to the air With deeper wounds, dressings produced better results Absorption of secretions varied considerably with different types of textiles. When absorption was poor the secretions spread beneath the dressing infection occurred and the mortality increased With thicker dressings and a more closely woven fibre improved absorption was associated with poor central evaporation and the persistently wet dressing resulted in wet infected wounds

Ideally fabric for wound dressing should not adhere to the tissues At present, the only non adherent materials are impregnated in a way which destroys their powers of absorption The fabric should be close woven, and should not swell greatly on wetting or shrink on drying—changes which greatly retard wound healing The finishing of the textile is important matting with titanium oxide and brightening with optical whiteners are often the cause of wound irritation

TREPONEMAL AGGLUTINATION TEST

The immobilisation test for *Treponema pallidum* (T.P I test) is at present the only practical specific test for the serodiagnosis of syphilis.[2] This test is technically difficult and considerable experience is required to read the reaction correctly The technical difficulties include the need to avoid using sensitised spirochætal antigens the deterioration of the survival medium used, the toxic action on the living treponemes of some sera and the anticomplementary action of other sera which may invalidate the test In addition there is always the danger that laboratory workers may be infected by the living organisms These difficulties can be largely overcome by the creation of special units but this is expensive and it draws away from general laboratories workers who can often ill be spared Accordingly this test has been restricted to a few specialised laboratories.

For many years investigators have attempted to evolve a simple specific agglutination reaction In 1953 McLeod and Magnuson[3] described their experiences with a treponemal agglutination (T P A) test *T pallidum* killed either by the antiformin method of Tani or by heat and oxophenarsine hydrochloride yielded satisfactory antigens On the other hand, formalin killed *T pallidum* did not agglutinate in the presence of syphilitic serum while phenol killed organisms showed some spontaneous agglutination McLeod and Magnuson found that the addition of fresh steer serum accelerated and enhanced agglutination and that the reaction was complete after two hours incubation at 37°C They concluded that the results of this test compared favourably with those of the T P I test both in specificity and sensitivity

Hardy and Nell[4] have lately reported their work on agglutination of *T pallidum* by sera from rabbits and human beings with treponemal infections Unlike McLeod and Magnuson they do not employ steer serum The technique is simple but requires eighteen hours' incubation at 37°C after mixing the antigen and serum Hardy and Nell conclude that the natural treponemal infections of rabbits and the close immunological relationship of these infections to syphilis explain the spontaneous clumping of the organisms in suspensions of *T pallidum* They also suggest that the more superficially placed antigen of *T pallidum* reacts with Wassermann reagin, whereas the deeper somatic antigen reacts with the specific treponemal serum agglutinin If this is so, the specificity of the standard tests for syphilis (S T S) will have to be re examined These workers use heat in the preparation of their antigen, but as a further precaution the sera to be examined are absorbed by S T S antigen before the agglutination test is done In addition they use ethylene-diamine tetracetate to overcome the inhibitory action of a divalent cation which is normally present in human serum They conclude, as a result of testing 430 human sera, that this relatively simple test has a specificity comparable to that of the T P I test and considerably greater than that of the S T S

Dardoni[5] tested the technique of McLeod and Magnuson and concluded that, because of auto-agglutination of the organisms in the suspension of *T pallidum*, it could not yet take the place of the T P I test Price and Boxall,[6] in this country, after a preliminary investigation of the technique of Hardy and Nell suggest that more research is required before it can be used routinely Nevertheless, it would seem that this type of test holds great promise

TUBERCULOUS PLEURISY

THORACIC surgeons have provided pathologists with material for studying almost all stages of pulmonary tuberculosis from the primary complex to the chronic cavity Good use has been made of the opportunity, as is evident from Medlar's[7] detailed monograph Lately pathologists have also been examining specimens from patients with tuberculous pleural effusions

Stead et al[8] describe 24 cases in which the chest was explored within a few months of the beginning of symptoms All the patients were thought to have tuberculous effusions, and tubercle bacilli had been recovered from half of them Thoracotomy was done because there were features in each case that "did not completely conform to the usual clinical picture" In fact, half were found to have non-tuberculous effusions, although in 3 of these acid-fast bacilli had been reported in sputum or pleural fluid 15 were tuberculous, and the pleural sacs were removed with varying amounts of lung tissue In 12 there was a caseous lesion in the lung just beneath the diseased pleura In almost all of these 15 the pleura itself was more than 1 cm thick and contained pockets of liquid caseous material In 7 all segments of the lung had many small nodules which were not apparent in the preoperative radiographs The clinical results are said to have been excellent in 12 of the 15 ; in 2 the decortication was inadequate, and in 1 staphylococcal empyema developed

Stead et al emphasise that it is not their policy to explore all cases of "idiopathic" pleural effusion They state that 10 of the 24 patients were operated on to remove the residual thick pleura , and their description of the removed pleura might certainly suggest that this tuberculous tissue was better out than in But none of the patients had been observed for longer than thirteen months after onset of symptoms , and it is well known that the pleura has astonishing powers of healing, and that all but a few patients without demonstrable lung lesions will remain well Wynn-Williams and Shaw[9] found a five year relapse rate of 15% in 128 patients, only 14 of whom were given antibacterial treatment, and Emerson[10] observed no relapse in 17 patients treated with antibacterial drugs and followed for two years

Not all would agree that the risk is so small In this country the five year relapse rate was long supposed to be about 30% But Roper and Waring[11] have recently reported reactivation of tuberculous disease in no less than 92 (65%) of 141 young men in the five years after a pleural effusion had developed while they were serving in the U S Armed Forces It is generally agreed that pleural effusions in young adults are almost always tuberculous and very seldom, if ever, "idiopathic", and that whatever may be the extent of the risk the condition should not be treated lightly But it is very doubtful whether surgical extirpation can play a useful part

OCULAR OCHRONOSIS

IN 1948 Anderson[12] first reported a new ocular syndrome in industrial workers engaged in the manufacture of hydroquinone Miller[13] has described in detail a small group of cases in this country In this syndrome the cornea and conjunctiva are stained in the area of the palpebral fissure The cornea has a brown sepia-like stain which traverses the whole thickness of its substance and in severe cases may seriously impede vision There are other changes which interfere with accurate vision—namely, vertical folds in Descemet's membrane, a white precipitate within the corneal substance due to protein denaturation, deformation of the anterior surface of the cornea producing irregular astigmatism, and in some cases ulceration In the early stages the conjunctival changes consist in drying and thickening in the palpebral fissure, and this area later becomes yellow Finally discrete dark patches develop over the white of the eye in the palpebral fissure on either side of the cornea, separated from it by a clear area Once the corneal staining has appeared, there is likely to be permanent visual disability , this is not alleviated by contact lenses, but might conceivably be reduced by corneal grafting The conjunctival staining gradually disappears without ill effect

There seems little doubt that the main cause of this syndrome is lengthy exposure to the vapour and dust of quinone—an intermediate product in the manufacture of hydroquinone Where the eye is protected by goggles or where the process is enclosed, the ocular changes do not arise There is some slight evidence that long continued exposure to an atmosphere heavily polluted with hydroquinone dust may produce corneal ulceration if the worker is unhygienic and careless in his protective habits , but some men have worked for twenty years in such an atmosphere without any change appearing As far as is known, there has never been an instance of this syndrome in workers who handle hydroquinone during photographic development

The clinical picture of this syndrome is of theoretical interest because it is almost identical with that of alkaptonuria and carbolic poisoning The ætiological link is the staining of the eye either exogenously or endogenously by a salt of hydroquinone For this reason the three conditions have been grouped together under the name ochronosis—a word coined by Virchow[14] who first described the pathological findings in alkaptonuria and wished to distinguish the disorder from melanosis

THE CAUSE OF POSTURAL PROTEINURIA

A FEW weeks ago we said that the mechanism of postural proteinuria was still unknown[15] An important contribution has since been made by Greiner and Henry[16] These workers criticise the view[17] that the proteinuria is directly due to increased pressure in the inferior vena cava and renal veins, and refer to an experimental study[18] in which increase of caval pressure to 150–220 mm saline, maintained for thirty minutes, caused no proteinuria

Carefully controlled observations in six young men with postural proteinuria indicated that the most important ætiological factor is pooling of blood in the extremities. Advantage was taken of the fact that postural proteinuria is particularly liable to occur in hot conditions[17] and all the observations were made at a temperature of 122 F Lordosis in the supine position produced proteinuria once only whereas venous-occlusion cuffs applied at a pressure of 80 mm Hg to all four limbs resulted in proteinuria in all the subjects Proteinuria, which regularly occurred after tilting the subjects to a 70 head up position was prevented by compression of the legs, which effectively inhibited peripheral pooling of blood

Greiner and Henry point out that their observations explain the facts that postural proteinuria is commoner in hot conditions producing peripheral vasodilatation and in motionless standing[17] which is particularly liable to cause pooling of blood in the legs They suggest that deviation of blood from the heart and lungs causes arterial vasoconstriction which is proportionately greater in the renal arterial system The erect lordotic posture greatly reduces the renal plasma flow[19] but this fall is no greater in cases of postural proteinuria than in non proteinuric controls.

LUNG CANCER IN ASBESTOSIS

THE causes of cancer of the lung are probably mainly exogenous[20] but each of the definitely known carcinogenic substances—e.g ores in Schneeberg and Joachimstal mines bichromates—accounts for only a minute proportion of all cases. Doll[21] now confirms suggestive evidence that lung cancer is an occupational hazard of asbestos workers Examination of the cause of death in 105 persons who had been employed in one asbestos works showed that 18 had had lung cancer associated in 15 cases with asbestosis The mortality of 113 men who had worked for at least twenty years in places exposed to asbestos dust was compared with the mortality experience of the whole male population There were 39 deaths in the first group whereas 15·4 were expected: the excess was due to deaths from lung cancer (11 compared with 0 8 expected) and from other respiratory and cardiovascular diseases (22 compared with 7 6 expected) The average risk among men employed for twenty or more years has been of the order of ten times that experienced by the general population This risk has become progressively less since the precautions introduced as a result of the Asbestos Industry Regulations 1931 to prevent dust dissemination in the works became effective

Gloyne[22] found in his series of 1205 specimens of lungs with dust diseases including 121 of asbestosis, that the rates for primary neoplasm of the lung in male and female asbestos workers were 20% and 10% respectively Barnett[23] found 31 deaths with carcinoma of lung in 235 deaths associated with asbestosis during the years 1924–46 with a distribution of 17 2% male and 8 4% female deaths Adjustments for length of exposure to the dust and age at death would scarcely account for the discrepancy in the figures between the two sexes The same discrepancy exists in the figures for all cases of carcinoma of the lung Kennaway and Kennaway[24] showed that the rates of female to male deaths in England and Wales had changed from 1 1 9 in 1921 to 1 : 4 0 in 1945 between 1935 and 1945 the increase was 250% for males and 170% for females If the causes of cancer in the lung are the same for both sexes (as in asbestosis and possibly in smoking), can the sex discrepancy be related to the baffling fact that while the total "amount" of tumour in both sexes is approximately equal 40% of the cancer deaths in females are from carcinoma of organs peculiar to the female,[25] leaving correspondingly smaller numbers for other sites? If so, what internal factor determines this organ selectivity?

Unlike asbestosis the main causes of dust diseases in the lungs are not associated with an increase in carcinoma of the lungs and Kennaway and Kennaway[26] showed that bronchial carcinoma is less common in coal workers than in the general population James[27] has confirmed this very neatly by comparing a series of South Wales coalminers with a series of non miners in the same area, obtaining figures of 3 3% for the former and 5 4% for the latter but he points out that the relatively low incidence of tumour in the miners may be partly due to dust disease causing death before the average cancer age The dust diseases generally act on the connective tissues, and there is no satisfactory explanation of why the asbestos fibres should affect the epithelium as well

EPILEPSY AND THE ELECTRO ENCEPHALOGRAM

IMPROVED techniques of electro-encephalography (E E G) have confirmed some earlier correlations of electrical with clinical activity, such as that of bilateral 3-per second wave-and spike patterns with petit mal have led to the modification of some such as that of square topped waves and a sharp down peak with psychomotor epilepsy and have cast renewed doubt on others such as the identification of the cortical spike focus with the site of origin of an epileptic discharge.[28]

Gibbs and his colleagues[29 30] have described valuable information about the natural history of E.E G abnormalities which has important clinical implications By following changes in E.E G patterns as infants and children develop they have obtained a longitudinal section of electrical brain activity to supplement the brief cross sectional view of isolated E.E G recordings They point out that the immature brain tends to react to various possibly epileptogenic traumata with a generalised electrical abnormality Moreover the pattern of reaction differs at different stages of maturation In infancy hypsarhythmia (continuous slow wave high voltage discharge with diffuse spiking) is common, as the first decade of life is traversed, at first "petit-mal variant" (2-per second sharp and slow waves) and then "classical petit mal" (3 per second wave and-spike activity) are more usual In adolescence and adult life the electrical response to cerebral insult becomes more localised This is so with epileptogenic factors occurring ab initio at this age, and may also apply to activity shown earlier as a generalised response in childhood *Focal activity, though less common, does also occur in* childhood, and, unlike the generalised response, it may clear spontaneously or change in form and site as age advances Thus, *occipital foci, present* rather more often in the 1–5 age group, had tended by the age of 9 either to disappear (40%) or to change their location (37%) to a temporal or possibly subcortical site, while midtemporal foci, by the age of 15, had either cleared (54%) or migrated to an anterior temporal or subcortical site (38%)

Gibbs and his school have done a great deal to advance the clinical value of electro encephalography, and these studies put us further in their debt The evidence that some focal abnormalities disappear spontaneously with age will be welcome to all those dealing with epilepsy in childhood It confirms clinical observation and underlines the need for caution in excising "epileptic foci," especially in the young Moreover, the change in focus once more raises the question of whether the primary site of epileptic discharge is cortical Gibbs et al speak of "*migrating foci*," which is a vivid description, but the change may be due to altered activity in one part of a complex neuronal circuit allowing activity already present in another part to emerge more clearly We still know too little of what the E E G pattern represents in terms of cellular neurophysiology

This work has further value in posing many clinical questions We are not told what proportion of those with focal and general E E G abnormalities had focal or general fits, nor is it clear, apart from the statement that "many develop multiple foci," what happens as age advances to the varying forms of generalised abnormality found in childhood Finally we need to find out the proportion of children who show these abnormalities *but have no clinical attacks at all*

GALL-BLADDER AND HEART-BLOCK

CONFLICTING views are held on the relations between the gall-bladder and the heart These fall under three headings—namely, the differential diagnosis between angina pectoris and the pain of gall bladder disease, the coincidence of gall bladder disease and coronary-artery disease in the same patient, and the possibility that gall bladder disease may aggravate existing heart-disease

White and his co workers[1] reported clear evidence of disease of the gall bladder in 6 8% of 1000 patients, who presented clinically with coronary artery disease They found at necropsy that disease of the gall bladder was almost twice as common in patients with severe coronary artery disease as in those with normal coronary arteries This association, they suggested, was related to an ageing process Breyfogle,[2] on the other hand, concluded from a comparable necropsy study that the association between gall-bladder disease and coronary artery disease was independent of age and sex Wolferth[3] wondered whether the two diseases shared a similar metabolic pathogenesis But there is a striking difference in the sex distribution of coronary artery disease, with male preponderance, which has not been found in disease of the gall-bladder

Whether gall-bladder disease aggravates angina pectoris is still uncertain, but there is now clear evidence that it influences arrhythmias McLemore and Levine[4] report 7 *cases of heart block and gall stones*, recent biliary symptoms had been present in all They concluded that the heart block was due to coronary artery disease or hypertension in 5, in 1 it was possibly congenital, and in the 7th it might have been due to diphtheria in childhood 5 had complete heart block with frequent Stokes Adams attacks, 1 had first degree heart block with sinus pauses and syncopal episodes and the 7th had an episode of transient complete heart-block accompanied by an upset of consciousness Preventive measures had failed adequately to relieve these attacks All these patients underwent cholecystectomy 4 were strikingly improved, with no subsequent attacks of loss of consciousness for six months or longer, preoperatively these 4 patients had experienced such attacks very frequently—up to four times a day The remaining patients were also improved, with definite diminution in the frequency of the attacks Anæsthesia was not thought to have contributed to their improvement Asystole during operation called for special measures in 3 of the patients but all withstood operation well McLemore and L reasonably conclude that in patients with Stokes Adams attacks, and especially where these have persisted despite treatment, disease of the gall bladder should be sought.

The physiological basis of cholecystectomy in heart block is not completely clear McLemore and Levine's clinical observation is supported by experiments on the frog,[5] and comparable but inconclusive observations have been made experimentally in man[6] Swallowing has been found to precipitate Stokes Adams attacks, Weiss and Ferris[7] recorded three cases in which Stokes Adams attacks were brought on in this way, and suggested that they were due to a vagal reflex In 1 of their patients a *traction diverticulum* of the œsophagus was present Distension of the diverticulum by a rubber balloon led to auriculoventricular dissociation and syncope Release of the distension was followed by a return to normal sinus rhythm and the disappearance of symptoms Atropine abolished the symptoms and the heart block Mackenzie[8] found in a patient with rheumatic carditis that either digitalis or swallowing delayed auriculoventricular conduction But it is still difficult to define the precise action of the vagus and the sympathetic nerves on the heart in the intact animal[9]

Another drug has been added to those that may be useful in the medical treatment of heart-block—namely, sodium lactate Bellet et al[10] have found *sodium lactate* of value in resuscitating the heart after cardiac arrest, in treating ventricular standstill in Stokes Adams attacks, and in otherwise *increasing* the ventricular rate in complete heart block The drug was given by intravenous injection or infusion

These two promising new methods of treating heart block will no doubt be widely tested Both may prove more commonly effective than the artificial pacemaker[11]

We regret to record the death of Dr C W BUCKLEY, who was senior physician to the Devonshire Hospital for Rheumatic Diseases, Buxton, and of Dr ROBERT FLEW, formerly physician to the Hospital for Sick Children, Great Ormond Street

CALORIES AND CRICKET

J. G. FLETCHER
M.Sc. Manc., A.R.I.C.
MEMBER OF THE DIVISION OF HUMAN PHYSIOLOGY, NATIONAL INSTITUTE FOR MEDICAL RESEARCH, LONDON

DESPITE the international prestige attached to success in sport,[1] detailed physiological studies of the energy expenditure in team games are few. Although the calorie cost of baseball (Morehouse and Miller 1953), and even that of the eightsome reel (Passmore et al. 1952) are available no detailed study of the energy expenditure in cricket could be found in the literature.

In a recent study of the energy expenditure of young men engaged in their usual activities the problem of the calorie cost of games assumed some importance (Edholm, Fletcher, McCance and Widdowson 1955). Opportunity was taken to measure oxygen consumption during archery, tennis, squash, and batting and bowling at the nets, and to observe and time events in an inter college competitive cricket match of rather better than village-green standard.

TABLE I—ANALYSIS OF TIME SPENT BATTING AND FIELDING IN INTER-COLLEGE MATCH

Activity	Time spent (to nearest ½ min.)			
	Player 1		Player 2	
	Batting	Fielding	Batting	Fielding
ing				½
ading	1½	14½	8½	4½
ing bowling	3½		0	
rolling		4½		15½
alking	3	15½	2½	0
unning	1	½	1½	½
tal	9	35	18½	30

COLLEGE CRICKET

In the college game the mean scoring rate was 2·44 runs per over and the average time per over was 3 minutes 27 seconds. In table I an analysis is given of the way in which time was spent by two players during the match. The term 'facing the bowling' describes the time when the batsman is receiving the bowling and includes all stroke play. The time spent during fielding in picking up and throwing the ball was very short and is grouped with running.

The calorie cost of batting and bowling at the nets was measured with the subjects wearing a mask connected to a Kofranyi-Michaelis portable calorimeter. Balls were delivered at the same rate as during play and batsmen ran twice for each six balls bowled. The results for 4 subjects are given in table II.

The energy expenditure during play was calculated by analysing the time spent in the various component activities and multiplying these times by the experimentally determined energy expenditure for that activity. In calculating the calorie cost of bowling in the game the value for bowling at the nets was not used because at the nets there was more than one bowler and hence a slower individual bowling rate. In addition bowlers at the nets usually do more fielding than during actual matches. The results of such calculations are shown in table III. It appears that activity at the nets was comparable with tennis, while during play the calorie costs did not exceed that of walking.

TABLE II—ENERGY EXPENDED DURING NET PRACTICE

Player	Surface area (sq. m.)	Measured expenditure (kcal. per hr.)	
		Batting	Bowling
1	1·80	413·1	549·0
2	1·87	301·2	402·0
3	2·08	591·6	421·4
4	2·11	553·2	547·8
Mean expenditure (kcal. per sq. m. per hr.)		239·6	212·2

Although cricket is nothing like so energetic a game as football the calorie values given in table III appeared to be surprisingly low. On the other hand great variety is to be expected in the tempo of our national sport and in the skill of the participants and consequently in the energy expended. These results might very well not be representative of cricket in general, and it was thought worthwhile to calculate the energy expended in Test cricket to see whether similar or different results were obtained.

TABLE III—ENERGY EXPENDED DURING INTER-COLLEGE MATCH

Player	Surface area (sq. m.)	Computed expenditure (kcal. per hr.)		
		Batting	Bowling	Fielding
1	1·86	395·8	319·2	186·0
2	1·87	315·0	283·2	229·8
3	2·08	415·8	318·6	205·2
4	2·14	405·0	338·4	201·0
Mean expenditure (kcal. per sq. m. per hr.)		183·3	158·0	111·6

TEST CRICKET

During the 1953 Test series against Australia English summer weather accounted for 46 out of the 150 hours scheduled for play. For a further 4 hours the ball was out of play leaving 100 hours during which runs were scored at the rate of 2·38 per over. The mean time of an over was 3 minutes 17 seconds, the daily average ranged from 2 minutes 50 seconds to 3 minutes 40 seconds. Further details are given in table IV. The original data from which these figures have been calculated are given by Swanton (1953) and White (1954). The scoring rate per over and the average duration of an over are seen to be virtually identical for inter college and Test cricket.

TABLE IV—1953 TEST SERIES ENGLAND v. AUSTRALIA

Batting		Bowling		Fielding	
Total runs	4363	Total overs	1833	Total balls	11 030
From boundaries	1988	Overs per day	83	Boundary strokes	401
Extras	202	Overs per hour	18·3	Balls not scored from	8781
Other runs	2173			Other balls	1754
Mean rate per hr	43·6	Mean time per over	3 min. 17 sec	Balls taken in field	8099†
Running between wickets per hr	*6·6	Mean runs per over	2·38	Balls taken per fielder per hr	8·1
		Mean overs per bowler per day	13		

* Including running for byes and before boundaries signalled.
† Assuming ½ × 8781 balls taken by wicket keeper.

The figures given in table IV were used as the basis for calculating the calorie cost of fielding, bowling and batting although some assumptions were necessary—for example that all running was at a speed of 7½ m.p.h. and walking at 4 m.p.h.

Individual performances during fielding could not be obtained from the records. The number of balls from which runs were scored is given in table IV. The number taken by the wicket keeper is not recorded but probably varies between a half and a third. It is assumed that the remainder must have been taken by the 9 fielders and the bowler and this quantity was added to the number of scoring strokes, including boundaries, to give the total figure for balls taken in the field.

Fielding

Fortunately the hours of play in the five test matches totalled 100 hours, which simplifies some of the calculations The fielding rate for the individual is given by dividing the total number of balls taken (8099 assuming the wicket-keeper takes one third, or 6636 if he takes one half) by 100 (hours) and 10 (fielders), which gives a fielding rate between 6 6 and 8 1 balls per hour So a fielder will, on an average, take a ball once every seven to nine minutes, and since the infielders are most frequently involved, activity in the outfield must be slight

Many fielders spend long periods slowly moving about close to their set positions, while others may stand firm but exhibit body movements of interesting variety An allowance was made for the energy expenditure involved, by dividing the calculated standing time, into strolling and standing, in the same ratio given in table I—i e, standing strolling = 19 23 The component activities of fielding were classified as standing (40 4% of the time), strolling (48 9%), running to field (1%) (assuming an average run of 20 yards to field each ball, which is probably an overestimate), walking after fielding, walking between positions (assumed to be 22 yards apart), and walking to and from the pavilion (a total of 9 7%)

The probable overestimate of time spent running is balanced by the lack of any allowance for picking up and throwing the ball. These figures are summarised in table v, the computed mean expenditure for fielding is 50% greater than for standing alone and is equivalent to very slow walking

Bowling

A run of 10 yards for all bowlers and a return walk of the same distance for each ball bowled was assumed in calculating the calorie cost of bowling (table v) Activities were classified as running up to bowl, walking back, walking to and from fielding position and pavilion, and standing fielding during alternate overs The calorie costs of standing, walking, and running, as measured by Edholm et al (1955), were used The value for fielding is obtained from table v An average of 83 overs was bowled each day, and the individual bowler delivered one seventh of these

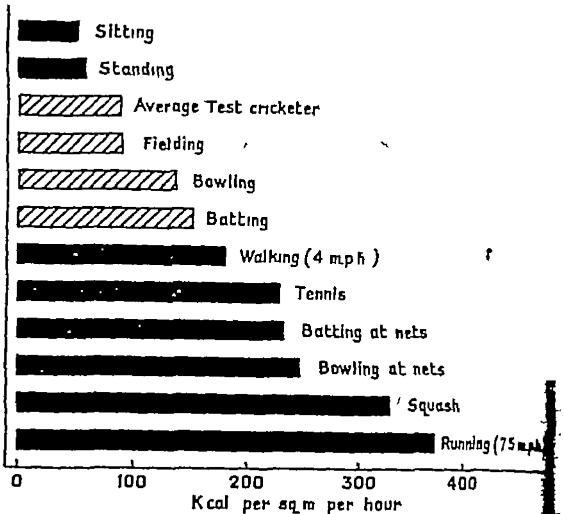
Batting

The figures given for batting in table IV show that there was running between the wickets for approximately half the runs scored The over all energy expenditure by batsmen (table v) was calculated from the measured costs for standing between overs, standing during batting of partner, batting, running, and walking to and from the pavilion The duration of each phase was computed, assuming the walking was at 4 m p h and the running was 22 yards per run at 7½ m p h The final calculation summarised in table v gives the average calorie cost as 155 2 kcal per sq m per hour

A separate analysis of the energy expenditure of the wicket keeper has not been made, as there is inadequate information available Umpiring and scoring have also been neglected

TEST PLAYERS

A final computation was made of the mean energy expenditure of that interesting but hypothetical individual, the average Test cricketer This player indulges himself in all four components of the game—he bowls 4 2 overs, taking approximately 14 minutes, he bats for 38½ minutes and scores 14 runs, he rests in the pavil for 116 minutes, and fields for the rest of the sched 6 hours of play per day His energy expenditure is at t rate of 86 4 kcal per sq m per hour—a value close that of fielding The accompanying figure shows h this expenditure compares with the computed expenditur of bowling, batting, and fielding in Test cricket, and w experimental values obtained from young men in o activities



Energy expenditure in young men (hatched = computed bl measured)

It remains to study briefly the probable energ expenditure of individual batsmen and bowlers of bo sides In the course of the 1953 series the maximu personal score in a day was 101 not out by Hassett in the second Test For the seven hours from the beginni of his innings it is estimated that the Australian capta expended energy at a rate 24% above the calculate mean, even assuming that he sat quietly while in th pavilion The increase was due to a high rate of scori and a high proportion of running between wickets. It was left to a Yorkshireman, Wardle, bowling ver economically in terms of energy and runs, to achieve the maximum number of overs in a day His analysi (36 overs, 14 maidens, 96 runs, 1 wicket) shows a hi proportion of maiden overs, while his energy expenditu as computed was approximately 9% lower than the me figure This is due to a short run up to bowl and relativel rapid overs According to the cricket correspondent of a London evening paper, Wardle took only 1 minute 48 seconds to deliver an eight ball over in Australia recently, as compared with times of 2 minutes 52 seconds, 4 minutes 17 seconds, and 4 minutes 25 seconds for Appleyard Statham, and Tyson respectively

TABLE V—ENERGY EXPENDED IN 1953 TEST SERIES

Activity	Batting		Bowling		Fielding	
	Time (hr)	Energy (kcal per sq m per hour)	Time (hr)	Energy (kcal per sq m per hour)	Time (hr)	Energy (kcal per sq m per hour)
Standing	47 8	67 6	22 6	57 6	40 4	57 6
Strolling *					48 9	88 5
Walking †	6 7	181 2	23 0	181 2	9 7	181 2
Running ‡	4 4	386 4	8 2	386 4	1 0	386 4
Batting	41 1	239 6				
Fielding			46 2	88 0		
Total	100 0		100 0		100 0	
Mean		155 2		127 0		88 0

* Equivalent to walking at 1–2 m p h
† Including between overs and to and from the pavilion
‡ Without additional allowance for throwing by fieldsmen

CONCLUSIONS

These calculations suggest that calorie expenditure sport is inversely proportional to the duration of effort. They indicate that in cricket better exercise is obtained at the nets than in the field The relatively small numbe of calories burnt by the average Test cricketer may hav some significant connection with the small bulk of th Ashes

CONN'S SYNDROME

(Primary Aldosteronism)

FROM AN AMERICAN CORRESPONDENT

At the recent meetings at Atlantic City of the American llege of Physicians, the American Society for Clinical vestigation, and the Association of American Physicians ch was heard of aldosterone (electrocortin) and of new disease entity involving the adrenal gland dis vered by Dr Jerome Conn of Ann Arbor Michigan is discovery may be as important to medicine as rvey Cushing's recognition of the syndrome which ars his name

In a presidential address last October to the Central ciety for Clinical Research Dr Conn described the case[1] a 34-year-old housewife who was admitted to hospital account of intermittent spasms weakness and alysis of muscles There were frequent attacks of eat muscular weakness and other attacks of typical tany involving the upper and sometimes the lower tremities She was well between attacks but the stolic blood pressure was known to have been 180– 0 mm Hg for four years For many years she had had uria and nocturia, and traces of protein were present the urine At the time of examination she was fit, ve for positive Chvostek and Trousseau signs. The ood pressure was 176/104 the size of the heart was rmal the reflexes were hyperactive and no oedema s present Biochemical studies revealed excessive ounts of aldosterone in the urine (equivalent to over 00 μg of deoxycortone acetate per day compared th a normal upper limit of 115 μg per day) There s severe hypokalæmia (serum potassium fluctuating tween 1 6 and 2 5 m eq per litre) The CO_2-combin g power was increased and the serum-sodium was ghtly increased to 151 A renal tubular defect in absorption of water was found and was thought to due to chronic hypokalæmia

Dr Conn pointed out the relative lack of important mptoms at extremely low levels of serum potassium e suggested that many cases of potassium losing phritis—such as that described by Evans and Milne[2]— ere really cases of primary aldosteronism At that me he prophesied that an aldosterone containing drenal tumour would be found when the patient was perated on, and he was right At the April meeting of e American College of Physicians he showed coloured hotographs of the large adrenal tumour which on say was found to contain tremendous amounts of dosterone compared with the aldosterone content of ormal adrenal glands

Last October Mader and Iseri[3] reported a case in hich the clinical picture was very *similar to that* scribed by Conn The patient was a 33 year-old woman ith tetany muscle pain weakness paresthesia hyper nsion and nervousness There was no history of omiting, diarrhœa or use of medicaments The serum iochemistry was disturbed: K 1 00, Na 143 Mg 1 12 a 3 05 CO_2 43 Cl 84 P 1 6 m eq per litre pH 7 5 rousseau's sign was positive, even after intravenous alcium gluconate but it gradually disappeared after rolonged treatment with potassium chloride Detailed orticoid-excretion studies revealed high absolute values for 17 hydroxycorticoid derivatives consistent with hyperfunctioning adrenal cortex Complete metabolic studies demonstrated (1) failure of correction of hypopotassæmia with a daily intake of 50 m eq K (2) pronounced negative Na balance and egress of Na out of cells during high K intake and balance (3) a slightly negative *magnesium balance on 12 m eq* Mg per day (4) loss of K in both urine and fæces; and (5) equilibrium of N balance Infusion of saline caused a distinct fall in serum Mg and plasma K without increasing urine Mg or K Profound electrocardiographic disturbance was only partly corrected by high intake of K Mader and Iseri felt that the syndrome was most likely due to adrenal cortical hyperfunction

Dr Iseri[4] said that they had recently operated on their patient—some three months after Dr Conn had had his patient operated on—and had found a large adrenal tumour which contained aldosterone Iseri now knows of two other patients with the same syndrome who had adrenal tumours and he has heard of a third patient in whom both adrenal glands were hypertrophied the glomerular layer being particularly large In this last case both adrenals were removed, and the patient recovered completely

The symptoms in these cases which are very similar to those previously described as "potassium losing nephritis," seem to indicate that aldosterone primarily affects potassium metabolism rather than sodium metabolism. But Dr John Leutscher does not believe that this is true The pathophysiology of the action of aldosterone was discussed at Atlantic City by Dr Laragh and Dr Stoerk and Dr Leutscher Laragh and Stoerk reported to the *American Society for Clinical Investigation* on the Mechanism of Secretion of the Sodium Retaining Hormone (Aldosterone) within the Body These investigators had previously demonstrated that *administration of potassium can produce a rise in serum* sodium that sodium-depleted subjects developed sustained hyperkalæmia after feeding relatively small amounts of potassium and that hypertrophy of the rat adrenal zona glomerulosa correlated with the level of serum potassium

Their present study was designed to determine the effects of changes in sodium and potassium intake and blood concentration on aldosterone secretion Synthetic diets were used in the study They found that restriction of dietary sodium in man even when combined with reduction in serum sodium produced slight to negligible aldosterone excretion unless potassium was provided in the diet When potassium was given in excess urinary aldosterone increased notably They took these findings to indicate that potassium is a powerful direct or indirect stimulus to aldosterone secretion Although dietary sodium restriction may exert its effect by modifying serum potassium or Na/K relationships within body water the data best support the hypothesis that change in serum potassium is a regulator—and possibly the primary regulator—of aldosterone activity

Dr Leutscher of San Francisco California, spoke at the meeting of the American College of Physicians, and reported that he had found high levels of aldosterone in cirrhosis nephrosis and congestive failure The increased urinary output of hormone seemed to correlate well with the presence of œdema and was inversely related to sodium excretion He also found that a high potassium intake lowered the urinary output of aldosterone

4 Personal communication.

THE MIDWIFE IN THE MATERNITY SERVICE

In a memorandum on policy the Royal College of Midwives welcomes the provision, under the National Health Service Act 1946 for maternity medical services to be given by general practitioner *obstetricians and for* the attendance of consultant obstetricians should the need arise "but expresses its belief that the maternity service must continue to be based on the provision of an adequate number of well-educated well trained and experienced midwives The midwife today is trained to be the practitioner of normal midwifery, and as a member of the obstetric team she should be given a share in the planning and organisation of the service

Antenatal Care

The College thinks it of vital importance for the midwife to continue to exercise her clinical skill during the antenatal period

"Many doctors are now undertaking antenatal care in their own surgeries, but this does not absolve the domiciliary midwife from taking her full share of responsibility In hospital practice where the obstetricians attend every antenatal clinic, we consider it essential that there should also be antenatal sessions conducted by midwives

"The midwife has always been a teacher of individual mothers but today she is taking a much larger part in the antenatal teaching of groups of mothers Classes for the mothers in antenatal clinics should be organised by the midwife in coöperation with other members of the health team The midwife herself should give the teaching on the physiology of labour and the preparations for it, the use of inhalational analgesics, the preparations for the baby, and breast-feeding Provided she has had the appropriate experience, the midwife may, and often does, give instruction on relaxation and antenatal exercises to small groups of mothers

"In our opinion the assessment of the suitability of the home conditions for confinement should be made by the midwife in consultation, where necessary, with the patient's own doctor"

Care During Labour

Every mother, in the College's opinion, should be under the constant care of a midwife during the whole of her labour Although a doctor may be present for part of the time, the midwife should continue to take full responsibility for the majority of normal deliveries She can administer inhalational analgesics and, under the Dangerous Drugs Acts, she can give certain pain-relieving drugs It is thus within her power, and it is her duty, to give the mother adequate relief from pain during labour

Postnatal Care

During the postnatal period the mother and baby should if possible be looked after by the same midwifery team who cared for them throughout pregnancy and labour

"We deplore the practice in some hospitals of sending the mother and baby home, or to other premises, within a few days of confinement, since this makes it impossible to give them continuity of care

"The care of mothers and babies should remain the responsibility of midwives for at least 28 days It is the duty of the midwife to encourage the mother to attend for a post natal examination and to make the necessary appointment

"We are strongly of the opinion that premature babies should be nursed by midwives"

Administration

The College favours the formation of area midwifery committees with a composition similar to that of the Standing Maternity and Midwifery Advisory Committee of the Central Health Services Council In order to facilitate the smooth running of the maternity service, voluntary interchange of staff within the service should be encouraged Further the college holds that in both institutional and domiciliary practice the control of midwifery staffs should be by experienced members of their own profession

"All ad hoc maternity hospitals and maternity units of general hospitals, where there are 50 or more beds, should have their own midwifery matrons Where midwifery units are too small for the appointment of matrons, the superintendent midwife should have complete control of the unit and be held responsible for all technical and nursing care of the patients and the discipline and good management of the department She should be recognised as the appropriate person, in consultation with the matron, to engage pupil-midwives and other midwifery staff Arrangement of off-duty and holiday leave should also be her province

"Midwifery staff in these units should not be interchangeable with the nursing staff of the general hospital to which the unit may be attached

The superintendent midwife should have direct access to the appropriate hospital committees when matters affecting the midwifery department are under discussion and she should make the reports on her own department"

Every local health authority should, in the College's opinion, appoint a non-medical supervisor of midwives who should be a State certified midwife with the necessary experience This officer should be responsible to an administrative medical officer and should have access to the appropriate committee when matters with which she is concerned are under discussion

Recruitment of Midwives

There is today a grave shortage of midwives in some maternity hospitals and homes, particularly in those which are not training schools The need is not so much to attract more recruits into midwifery training as to retain the trained personnel in the practice of midwifery The College lays emphasis on the following points

(*a*) *Promotion*—There should be greater scope for the promotion of midwives within the profession More midwifery matrons should be appointed, so increasing the prospects of promotion and encouraging the midwife with administrative ability to remain in midwifery Newly qualified midwives should be given opportunities to take their fair share of responsibility in order to equip themselves for promotion to more senior posts "We believe that the midwife with additional qualifications should be considered for promotion on her merits as a midwife"

(*b*) *Auxiliary Staff*—The provision of adequate auxiliary staff, nursing and domestic, in maternity hospitals and homes would allow trained staff to devote more time to their specific duties for the mother and baby, and would thus make the conditions of practice more attractive to midwives.

(*c*) *Salaries and Conditions of Service*—It is most important that the heavy responsibility undertaken by the midwife and the irregular and long hours which she often has to work should be suitably recognised in her salary and conditions of service

---

DOCTORS IN PARLIAMENT

In last week's General Election ten doctors were elected to Parliament Two of them are newcomers to the House of Commons—Dr D McI Johnson, Conservative member for Carlisle, and Mr J D Cronin, F R C S, Labour member for Loughborough

R F B Bennett, V R D, M.A, B M Oxfd, D.P M (C., Gosport and Fareham), was first elected in 1950

A D D Broughton, M A, M B Camb, D.P.H., D.P.M (Lab Batley and Morley), first entered Parliament by winning a by-election in 1949

J D Cronin, M B Lond, F.R C S (Lab, Loughborough) qualified from St Bartholomew's Hospital in 1939 He served in the R A.M C from 1942 to 1946 After holding appointments at the Royal Free Hospital and Great Ormond Street, he became orthopædic surgeon to the French Hospital in London He has been a member of the London County Council since 1952

Walter Elliot, P C, C H, M C, M B, D SC Glasg., LL.D F.R C P, F R S (C, Glasgow, Kelvingrove), first entered Parliament in 1918 *He held office as Minister of Health in 1938-40* He has represented his present constituency since 1950

Somerville Hastings, M S Lond, F R C S (Lab, Barking) a former chairman of the London County Council, was first elected in 1923

Charles Hill, P C, M A, M D Camb, LL.D, D P.H (L and C Luton), was secretary of the British Medical Association from 1944 until he entered Parliament in 1950

D McI Johnson, M A, M B Camb (C, Carlisle), qualified from St Bartholomew's Hospital in 1926 He is also a barrister at-law

Colonel Malcolm Stoddart Scott, O B E M.D Leeds (C, Ripon), was Conservative member for Pudsey and Otley from 1945 to 1950, since when he has represented Ripon

Barnet Stross, M B, M SC Leeds (Lab, Stoke on Trent Central), has been in Parliament since 1945

Edith Summerskill, P C, M.R C S (Lab, Warrington) represented Fulham West from 1938 until the recent dissolution

The photograph of Dr Bennett is by the *Evening News and Hampshire Telegraph*, Mr Cronin by Universal Pictorial Press and Agency Dr Hill by Elliot and Fry Dr Johnson by Lafayette Colonel Stoddart Scott by Navana Dr Stross by the *Daily Herald*, and the remainder by Press Portrait Bureau.

A NEW CHILD-HEALTH CENTRE

Ex Natal, ante natal, post natal is the comprehensive motto suggested by Prof Alan Moncrieff for the new Province of Natal Centre of the London University Institute of Child Health The centre was opened on May 26 by Mr G P Jooste, High Commissioner for the Union of South Africa, who said that the financial help given by the people of Natal, in founding it, was part of the "Salute to Britain Fund," which they collected as a gesture of sympathy for our war-time troubles

PILGRIM'S PROGRESS

How the fund came to be used in this way is a stirring story In 1939 the medical committee of the Hospital for Sick Children, Great Ormond Street, were already debating how the hospital might best collaborate with the preventive health services, and at the same time a committee at the British Postgraduate Medical School were discussing a plan for preventive pædiatrics By 1943 (and considering how our attention was occupied at the time, this must be regarded as fairly rapid going) informal discussions had taken place with senior medical officers in the London County Council, and the phrases "model infant welfare centre" and "model school treatment centre" were heard In 1946 the University of London Institute of Child Health, with Professor Moncrieff as director, was founded, and though it was tucked into the hospital, and using cubicles for offices, it began at once to investigate how a model welfare centre might come into being The borough councils of Holborn and St Pancras allowed the institute to use their centres for the teaching of preventive work, but money for building was scanty, and building prospects scantier But in the summer of 1947 this star-crossed project suddenly found friends Mr Rupert Ellis, the Mayor of Durban, mentioned, in the course of a friendly visit to Professor Moncrieff, that he was sorry the advent of the National Health Service had prevented the people of Natal from helping Great Ormond Street Hospital "*I remember gripping my chair hard*," Professor Moncrieff said at the opening ceremony, "as I launched into a tactful explanation of how the money *could still be used—for our model welfare centre*" The sequel was a message from Mr Ellis to the South African Gift Committee, and on Dec 4 news came that the institute was to have £106,888—the balance then remaining of the Natal Gift

During the next eight years—years littered with planning committees, building committees, architects' conferences, and applications for building licences (finally issued in 1953)—the London County Council had time to consider their own part in the scheme, and undertook to pay 90% of the cost of maintenance and all the salaries of medical and nursing staff By the time building actually began the original gift had increased to £120,000 by interest, though unfortunately the rise in building costs had kept pace

MODEL INFANT-WELFARE CENTRE

The new building stands, on land provided by the university, at the corner of Guilford Street, overlooking another site benign to children—that of the old Foundling Hospital In the long run it will house both the Province of Natal Centre and the Institute of Child Health, but so far only the centre has moved in The spacious ground floor is planned for maternity and child welfare work, with plenty of rooms for clinics (antenatal in the south wing, postnatal in the north), a waiting room large enough to be used for demonstrations, lectures, and meetings, and a playroom for toddlers opening into what—when the builders relinquish it to the gardeners—should be a pleasant leafy garden with a fig-tree in the middle This playroom, like almost every other room, and all the corridors, in the building, is heated from steam-warmed aluminium panelling in the ceiling—the steam being cleverly borrowed from the heating plant of the hospital A reinforced glass panel, reaching to the floor, gives even the smallest child an outlook into the garden, and is guaranteed to stand up without splintering to thumps, kicks, and toy trains flung in anger The playroom, with perhaps one or two others near it, is to be used as a crêche on two half-days a week, and if this proves a popular arrangement it may be extended We all know the drawbacks of the full time day nursery anyhow from the children's point of view, but a couple of afternoons a week in the company of other children is sometimes just what the pædiatrician prescribes for a child, and it can also provide a welcome break for the mother Unfortunately such sporadic attendance is not usually acceptable to day-nurseries, and hence few mothers can arrange it for their children The Province of Natal centre may be starting a new and useful pattern The ground floor also houses a shop for welfare foods and a demonstration kitchen Just outside the entrance is a covered perambulator store, on which an eye can be kept from the inquiry desk, just inside

MODEL SCHOOL TREATMENT CENTRE

On the first floor are rooms for those activities of the school health service which Professor Moncrieff describes as "more conveniently carried out at a clinic than in the schools"—such things as dental and orthoptic rooms, a minor ailments clinic, and a room specially equipped for the testing of deaf children. The child guidance clinic which has been carried on at the John Street centre will also be transferred here to continue its work On the floor, too, is the health visitors' room (there will be three of them and their superintendent) and also their common room where they can lunch and brew tea In addition there are changing-rooms and lavatories for the children—boys at one end of the building, girls at the other following the usual L C C plan

THE INSTITUTE

This floor will also contain the reference library of the institute, which is to occupy the third floor The two large research laboratories are equipped with a new practical type of bench, not built to the wall but fitted against it, with cupboards underneath which can be moved along on skids to any convenient position The water pipes to the sinks, and the gas pipes, running along the wall behind the benches, are thus easily accessible to the engineers, and the layout of the laboratory can easily be altered by changing the position of the benches On the landing outside is a cold room for storage of specimens

All the windows in the building work on pivots at the mid-point of the two long sides they can be turned completely over for cleaning, and adjusted at any angle for ventilation The decorations are the only part of the new building which seem disappointing, being mainly a timid shade of green, but no doubt gay curtains, some of which have already appeared, will make a great difference

This is an important venture, a remarriage of therapy and prophylaxis—two partners who should have known better than to get divorced

CENTRAL HEALTH SERVICES COUNCIL

The thunder of the *latest annual report* by the Central Health Services Council[1] is rather distant, for accounts of the two main tasks completed during the year—investigations of general practice in the National Health Service,[2] and of the internal administration of hospitals[3]—were published some time ago

---

[1] Report of the Central Health Services Council for the year ended Dec 31, 1954 H.M Stationery Office Pp 26.

[2] Report of the Committee on General Practice within the *National Health Service* H M Stationery Office, 1954 *See Lancet* 1954, ii, 32

[3] Report of the Committee on the Internal Administration of Hospitals H M Stationery Office, 1954 See *Lancet*, 1954, ii, 741, 747

Mental Nursing

During the year the council set up a working party to djudicate on a difference of opinion between the tanding Mental Health Advisory Committee and the tanding Nursing Advisory Committee over nurses for ental and mental-deficiency hospitals The working arty unanimously favoured the training and employment f nursing assistants.

hortage of Dentists

In 1946 the Teviot Committee reported that until bout 20 000 dentists were in active practice there would e no likelihood of securing entrants more quickly than ey were needed The Standing Dental Advisory ommittee saw no need to amend this appraisal It ound that of 15 000 dentists on the Register many ere no longer in practice, some were practising outside e United Kingdom and many admitted to the Register ith Colonial qualifications were studying for higher egrees. Of the remainder who were practising some % were aged over 55 The committee concluded that nless some action is taken there will be an acute hortage of dentists in the near future ' The Minister of ealth and the Secretary of State for Scotland have since t up an interdepartmental committee to ascertain the asons for the lack of candidates of suitable quality and indicate remedies.

GENERAL MEDICAL COUNCIL

SESSION MAY 24–27

The General Medical Council met on May 24 and 25 nd its session was followed by the sittings of the Medical isciplinary Committee

After a presidential address by Sir David Campbell ummarised in last week's issue) the council considered rovisional proposals for abandoning the certificate in ublic health and consequent rearrangement of the urriculum for the diploma

Dr R. M F Picken, moving adoption of the report of a pecial committee set up last year, said that written and ral evidence had been obtained from interested bodies and persons. In general, the opinion was that no substantial amendment was required in the subject-matter prescribed n the existing rules, but it appeared that the provision whereby every candidate for the D.P H had first to obtain he certificate was serving no useful purpose and was proving inconvenient for teaching bodies The rules were considered sufficiently elastic to enable any licensing body to make provision for part-time courses The ommittee had drawn up draft rules abolishing the ertificate and making consequential amendments Candidates should have a fairly wide experience of linical medicine before starting their studies for the diploma and the proposed new rules laid down that candidate should not be eligible to enter for the examination until two years after he had been fully registered Dr Picken explained that the net effect would be the same as with the existing rule but persons who did not have to do a period of National Service would not be given an advantage.

The council agreed to circulate the draft rules, with an xplanatory letter, to the licensing bodies and teaching institutions and provisionally approved the draft introduction subject to any necessary adjustment when the rules were submitted in due course for final approval

Dr H Guy Dain moved the adoption of the report of the Pharmacopœia Committee containing the report of the British Pharmacopœia Commission He pointed out that doctors would have eight years in which to get used to writing their prescriptions in the metric instead of the apothecaries system Sales of the *British Pharmacopœia 1953* to date totalled 33 728 The *Addendum 1955* would be published on Oct 3 and would take effect on March 1 1956

On the second day of its session the council met in camera to consider various matters including it is understood questions concerning the medical curriculum

Medical Disciplinary Committee

The Medical Disciplinary Committee ordered three erasures from the Register There were no applications for restoration following disciplinary erasure.

TESTIMONIALS

In the past when the committee has postponed judgment the doctor concerned has been told to furnish the names of professional colleagues and other persons of standing who would 'be willing to testify to their knowledge of your conduct during the interval.' The form used at the present session differed by the addition of the word confidentially" Whereas previously the testimonials have on occasion been read in open session with the doctor present, this practice is no longer adopted by the committee—a change that was commented on several times at the sitting

One counsel Mr J L E Rees at the conclusion of a case in which judgment had been postponed said that, although it was appropriate that the testimonials should be confidential there might be something in them which the committee would take against the doctor He suggested that an abstract of such adverse references should be supplied otherwise the defence would be at a disadvantage

Mr C P Harvey the legal assessor said that this would be possible The question was whether it would be politic He was sure the committee would consider the point

In two cases in which he appeared, Mr E B McLellan, counsel, offered to help the committee if there was any point in the testimonials on which he could assist. The Legal Assessor replied that the testimonials were given confidentially They would lose a great deal of their value if they were given by people who knew that they were afterwards to be the subject of comment and argument by other people

NO ERASURE

Herbert Albert Kenneth Rowland, registered as of The Vicarage Cleator Cumberland B.M Oxfd (1945) had had judgment against him postponed from July 1954 for obtaining payment in respect of prescriptions improperly and dishonestly claimed to have been dispensed by him He was not present; but Mr McLellan counsel instructed by Messrs. Le Brasseur and Oakley solicitors to the Medical Protection Society said that a year ago in order to rehabilitate himself he obtained a medical post in the Transvaal Mr McLellan submitted that the practice of asking for testimonials was applied most easily when the doctor remained in general practice or in hospital work in this country It was not so applicable when he went to another country Dr Rowland was in the difficulty that the only two doctors with whom he was in contact were doctors in a subordinate position to himself The President announced that the committee judged Dr Rowland to have been guilty of infamous conduct in a professional respect but after careful consideration of the testimony to his conduct and what had been said on his behalf they had decided not to erase his name from the Register

The Registrar was not directed to erase the name of *Moreen Catherine O Brien* registered as of Endfield Woodhouse Sheffield M.B Sheff (1950) who was found guilty of infamous conduct in a professional respect in forging medical certificates for National Insurance purposes which purported to relate to herself Judgment had been postponed for a year

FURTHER POSTPONEMENT

Judgment had been postponed for a year in the case of *William Frank Cruickshank* registered as of Westwood Brechin, M B Glasg (1933) who had been found to have been convicted of being drunk and disorderly and to have been guilty of failing to visit or treat patients neglecting over a considerable period his duties as a medical practitioner under the National Health Service and disregarding his personal responsibilities to patients. Dr Cruickshank attended but was not represented The President told him that the committee was not satisfied that the testimony as to his conduct would warrant them discharging the case at the present time A further postponement of a year was ordered, in his own interests

ERASURES

The Registrar was directed to erase from the Register the name of *Robert Taylor Noel Simpson*, registered as of Wakering House, Great Wakering, Essex, M.B Belf (1942) This is subject to appeal to the Privy Council within twenty eight days Mr McLellan, who appeared for Dr Simpson, said that his state of mind was such that retention of his name on the Register could not be recommended

Ebenezer Francis Thomas, registered as of Round House, High Street, Tullamore, Offaly, M.R C S (1951), was charged with infamous conduct in abusing his professional relationship with a married woman, and with committing adultery with her, of which he had been found guilty by decree of the Divorce Court He was found guilty of infamous conduct, and the Registrar was ordered to erase his name from the Register This is subject to appeal within twenty-eight days

FURTHER CONVICTION

In May, 1954, the committee decided to postpone judgment for a further period of a year in the case of *Patrick Aloysius Gallen*, registered as of 89, Grant Street, Glasgow, C 3, M B Glasg (1929) He had had convictions in 1940, 1946, and 1952 for driving while under the influence of drink and for driving without due care and attention Mr Widgery said that there had been a further conviction against the doctor for assault In view of testimony to Dr Gallen's conduct, the committee did not direct the Registrar to erase his name from the Register

ABUSE OF DRUGS

Thomas Leven, registered as of 2, Beech Avenue, Irvine, Ayrshire, L R C P.E (1945), had had judgment postponed for a year in May, 1953, after a conviction for obtaining morphine sulphate, contrary to the Dangerous Drugs Regulations Judgment was further postponed in May, 1954, and November, 1954, in the light of medical reports Dr Leven now attended and told the committee that it was more than fifteen months since he had received his last withdrawal dose In view of the testimony to his conduct, the committee did not erase Dr Leven's name

NAMES NOT ERASED

In view of favourable testimony, the Registrar was not directed to erase the name of *Graham George Robertson*, registered as of 22, North Ridge, Bedlington, Northumberland, M B Edin (1934), against whom judgment had been postponed for a year after conviction for driving a motor car while under the influence of drink and in a dangerous manner

James Ross, registered as of 151, Park Grove, Barnsley, Yorkshire, M B Edin (1943), had had judgment postponed for a year after conviction for a series of drug offences In view of the testimony to his conduct, the committee did not direct the Registrar to erase his name

The Registrar was not directed to erase the name of *Herbert Trevor Duke*, registered as of 7, Manchester Street, London, W 1, M B Lond (1952), who appeared before the committee

In view of favourable testimony as to his conduct, the name of *Robert John Gordon Williams*, registered as of Rockdale, Abersoch, Caernarvonshire, M.R C S (1941), was not erased Judgment had been postponed from July, 1954, after two convictions for driving a motor vehicle when under the influence of drink

FURTHER POSTPONEMENT

Ralph Martin Case, registered as of 71, Gillott Road, Edgbaston, Birmingham 16, M.R C S (1934), M B Birm (1934), appeared for postponed judgment He had been convicted of unlawfully procuring dangerous drugs The President announced that the committee had postponed judgment for a further year

Patrick Joseph Conlin, registered as of c/o Barclays Bank Ltd, Dudley, Worcs. M B N U.I (1920), had been convicted of driving a car whilst under the influence of drink The committee postponed judgment for a further year

NAME ERASED

Francis Carminow Doble, registered as of 42–43, Dean Street, London, W 1, M R C S (1906), was charged with having been convicted at the Central Criminal Court on Nov 11, 1954, of unlawfully using an instrument to procure a miscarriage, for which he was sentenced to twelve months' imprisonment The Registrar was directed to erase from the Register the name of Francis Carminow Doble He has twenty-eight days in which to appeal

SHOOTING CHARGE

Robert Philip Strang, registered as of 40, Harley Street, London, W 1, M.R C S (1940), M R C.P (1946), had been sentenced to eighteen months' imprisonment at the Central Criminal Court in November for shooting Edward [illegible] with intent to do him grievous bodily harm Judgment was postponed for two years

DRUG OFFENCE

James McKenzie, registered as of 255, Rochdale Road, Middleton, Manchester, M B Aberd (1944), admitted convictions in 1954 of unlawfully procuring amidone for himself and of unlawfully procuring a dangerous drug The committee postponed judgment for two years, requiring Dr McKenzie to give names of persons who would be prepared to testify confidentially as to his conduct in the meantime

BREACH OF THE PEACE

Robert Lindsay, registered as of 8, St Ninian Drive, Inverness, M B Glasg (1945), admitted convictions for committing a breach of the peace in 1951, 1952, and 1955, and one of being found drunk in 1954 The President announced that judgment was postponed for a year

MOTORING OFFENCES

William James, registered as of Richmond Villa, Llandyssul, Cardiganshire, M R C S (1942), was summoned on a charge of having been convicted at Carmarthen in 1953 and again in 1955 of being in charge of a motor vehicle when under the influence of drink The committee postponed judgment for a year

---

Public Health

QUARANTINE MEASURES IN POLIOMYELITIS

A P Goffe
M B Lond, Dip Bact
SENIOR BACTERIOLOGIST

Edith M Parfitt
B Sc Lond
SCIENTIFIC ASSISTANT

VIRUS REFERENCE LABORATORY, CENTRAL PUBLIC HEALTH LABORATORY, COLINDALE, LONDON

There has been much discussion about the possible value of quarantine measures in the prevention of poliomyelitis Agerholm (1953) suggested that all persons with any degree of contact with a patient after the 4th day preceding the onset of symptoms should be strictly quarantined for 15 days The expert committee on poliomyelitis of the World Health Organisation (1954) recommends that "Children with familial or intimate exposure should be confined to their homes for 21 days Adults need not be confined, they should refrain from association with children other than their own and should avoid intimate contact with adults"

Apart from the question of the advisability of applying quarantine measures, the practicability of their application would depend on the distribution and spread of virus in the community The measures might need to be applied to all infected persons if a significant limiting effect were to be obtained in the community However, the view has been expressed that "infection moves through a relatively narrow stream of the population" (Bradley 1952), and it has been shown that virus can be isolated much more often from associates of cases than from non-contacts and with the greatest regularity among household contacts (Brown et al 1954) On the other hand serological studies have shown the high frequency of subclinical infection The work of Melnick and Ledinko (1953) showed that at the time of a type 1 summer epidemic, the ratio of subclinical infections to clinical cases was as high as 175 to 1 in children aged less than 1 year and somewhat lower in older children This suggests that virus is much more widely disseminated than is apparent from the number of clinical cases

We describe here a small outbreak of poliomyelitis in a country district during January and February 1954 Part of the affected area had been under regular survey since 1951 Quarantine was applied under relatively favourable conditions Laboratory investigations were designed and applied to estimate the extent of infection with the virus in household contacts of cases and in sections of the community at large during and after the period of quarantine The findings indicate that the quarantine measures applied in this community did not prevent the spread of infection

Laboratory Methods

Examinations for virus were made by inoculating tissue-cultures with extracts of fæces or of sewage All the specimens were frozen as soon as possible and were transported and stored frozen till just before test.

Tissue-cultures —Epithelial-cell cultures were grown in plasma-lined roller tubes from explants of minced monkey kidney in a medium consisting of 95% synthetic medium 199 (Morgan et al 1950) and 5% horse serum Cultures were ready for use after 8–10 days incubation at 37 C After the addition of either stool or sewage extracts cultures were re fed if necessary usually at 5-day intervals. The presence of poliomyelitis virus was suspected if cultures underwent characteristic cytopathic degeneration (Robbins et al 1952) and was confirmed by neutralisation in tissue-cultures or by complement fixation (Le Bouvier et al. 1954) with type-specific hyperimmune monkey sera Similar cultures and cultures of HeLa cells (Scherer et al 1953) were used for antibody tests; fresh medium was added just before inoculation and was not changed subsequently

Fæces —10% aqueous suspensions of each specimen were centrifuged and each supernatant fluid to which antibiotics had been added was inoculated into 2–4 cultures Some of the specimens yielding negative results were re-tested after ten times concentration of the extract by ultracentrifugation for an hour at 40 000 r p.m. in a Spinco centrifuge

Sewage.—To obtain samples, gauze swabs were left in the sewers for three days (MacCallum et al. 1952) at thirty points which had been selected in 1951 for a survey (MacCallum et al 1953) Fluid squeezed out of the swabs was pooled and concentrated from about 1 5 litres to a final volume of 6 ml. by precipitation with ammonium sulphate followed by ultracentrifugation (Melnick 1947) Samples taken at individual points were treated individually by ultracentrifugation alone (Melnick 1947) Each sample was inoculated into 10–20 cultures 0·1 ml being used per culture

Water —100 ml of each sample was centrifuged at 40 000 r.p.m. for an hour and the entire deposit was inoculated into ten cultures

Tests for antibody —Sera from the cases and contacts were subjected to a neutralisation test in which mixtures of blood or serum dilutions and a standard dose of virus (100 TCD_{50}) were inoculated into tissue-cultures. From the school children 0·1 or 0 2 ml of whole blood was collected by ear prick and immediately diluted with 0 6 ml of saline solution containing a trace of heparin After sedimentation of the blood-cells the supernatant fluid was tested for neutralisation of type-1 poliomyelitis virus by inoculation into suspensions of HeLa cells. This modification of the technique has been found sensitive to traces of antibody and was therefore valuable for tests on such small samples of blood

Description of Area

Topography

The terrain is farming country in East Suffolk The Town A, of about 7400 inhabitants is surrounded by a rural district which includes several parishes of 50–400 inhabitants The town which lies on a main road and railway has some industry and a market It is served with piped water and drainage On the sewage system thirty points established for the 1951 survey had been used for regular quarterly sampling Each point received drainage from 9–100 houses. In the present investigation an additional point was selected receiving drainage from a few of these points and from other parts of the town about 650 houses in all No houses where cases of poliomyelitis had occurred nor any of the town's schools drained into these points The sampling was estimated to have covered 1450 houses with 4430 inhabitants, more than half Town A's population

Village B, of 96 inhabitants, obtains its water from various places and has no piped sewage Most families from the village visit the town for shopping to see the doctor, &c Children aged more than 11 years attend secondary schools in the town and children aged less than 11 years attend a primary school in the neighbouring parish ; this school had 21 children under one teacher Teaching was usually conducted in one room, and midday meals were served in a second room Bucket closets were provided outside the buildings but hands could be washed only in a small cloakroom inside the school and supplied with water pumped from a well apparently directly under the school house The contents of the latrine buckets were used to manure a plot of land 150 yards from the school Drinking water was brought in sterilised containers to the school from the town

History of Poliomyelitis in the Area

Records over the past thirty years showed that single paralytic cases had been notified from Town A in each of the years 1925 1948 and 1951 The rural district embracing Villages B and C had a less fortunate record for its total population of 19 280 In 1937 there was one case in 1947 four cases, 1949 five, 1950 three 1951 one and in 1952 four cases all paralytic

We had been interested in this area since 1951 Virus was isolated from the case in the town in 1951 and found to belong to type 2 (Goffe 1953) Sewage had been examined at intervals of three months since the spring of 1951 In 1951 sewage sampled 10 days after the onset of the case was shown by monkey inoculation to contain poliomyelitis virus, but this was not typed Virus was not isolated again until July and November 1953 when on both occasions a type 2 poliomyelitis virus was found

Present Outbreak

The order of events in 1954 was as follows

Jan 8 case 1 aged 3 years, from Town A, admitted to hospital with paralytic poliomyelitis.

Jan 11 case 2 aged 33 from Village B admitted to hospital with paralytic poliomyelitis.

Jan 12 case 3 aged 11 years from Village B admitted to hospital with paralytic poliomyelitis

Jan 13 case 4 aged 16 from Town A, admitted to hospital with non paralytic poliomyelitis. Conference to decide on quarantine measures.

Jan 14 quarantine imposed on families of cases 1–4 Collection of specimens started 8/17 household contacts found to be virus carriers

Jan 19–21 Virus found in sewage of parts of Town A, away from households of cases, and in sewage of household of case 4

Feb 4 21st day of quarantine 6/17 household contacts still virus carriers.

Feb 12 onset of paralytic poliomyelitis in case 5 aged 20 in Village C

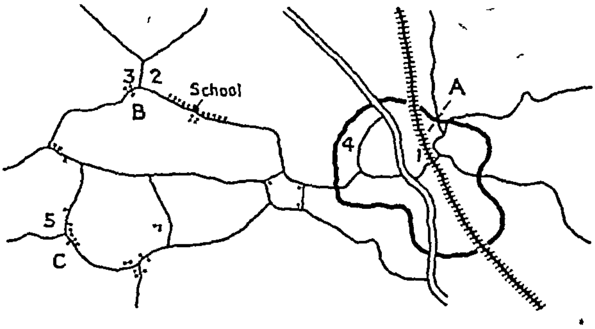
March 2 5/17 household contacts still virus carriers 1/18 school children of Village B found to be a virus carrier

March 8 quarantine lifted (54th day)

March 16–18 virus found in sewage of parts of Town A, away from households of cases

April 7 1/17 household contacts still a virus carrier (84th day)

It will be seen that during the second week of January 1954 four patients with poliomyelitis were admitted to



Sketch map showing location of cases 1–5 and village school and relation of town to surrounding villages

hospital, two from Town A and two from Village B Three of these cases were paralytic and one non paralytic, none of the patients became dangerously ill, but case 1 had considerable residual disability affecting both legs In the middle of February another case came to light in Village C, a woman complaining of weakness in the arms only Cases 1 and 4 came from different areas of the town, and had no known contact with each other directly or indirectly, or with members of the village families (see figure) Cases 2 and 3 were close neighbours in a group of council houses, obtaining a common water-supply from a deep bore-hole Case 3 attended a school in the town, his brother and sister went to the same village school as a daughter of case 2

On Jan 13 a conference was held between the medical practitioners of the town, the medical officer of health, the sanitary inspectors of the urban and rural districts, the director of the Ipswich Public Health Laboratory, and ourselves to decide on quarantine and other precautions to be taken, and on the scope of the investigation From the evening of the same day quarantine was applied to the families of these four patients Restrictions on the children were maintained until March 8, a total of 54 days In each of the four families children stayed away from school, had no contact with other children, and paid no visits to houses of other families or places of public congregation Adults avoided contact with others as much as possible, fathers continued at their work, and mothers were allowed to go shopping, but in some instances this was done for them by neighbours, who left the goods on the doorstep The only visits permitted to each house during the 54 days' quarantine were the periodic calls of the family doctor and the sanitary inspector in connection with the investigation

Samples of fæces were collected weekly for seven weeks and later from those still found to be excreting virus at the end of this period Blood samples were taken from the family of case 4 at the beginning, and from all the families at the end of the period A sample of tap water was collected from the house of case 1 on Jan 13, and a sample from the deep bore hole in Village B on Jan 14 Sewage from parts of Town A was collected, as described above, on four occasions Jan 15, Feb 16, March 16, and May 11 In addition sewage draining from the house of case 4 was sampled separately on each of these occasions Five days before three quarantined contacts returned to the village school samples of fæces and blood were collected from them and from all the other school-children and the teacher, three weeks later a second series of specimens was collected

Laboratory Findings

Examination of cases—Type 1 poliomyelitis virus was isolated from one or more specimens of fæces from four out of five cases (cases 1, 3, 4, and 5) Case 2, from whom virus was not isolated, was a typical case of mild paralytic poliomyelitis in a woman aged 33 Six specimens of fæces all yielded negative results However, she had type-1 neutralising antibody in her serum, and two of the four other members of her family were carrying the virus We conclude that her attack was also due to type 1 poliomyelitis virus

Examination of contacts—Type 1 poliomyelitis virus was isolated from the first specimens collected from eight out of seventeen household contacts None of these had any illness during the period of observation nor admitted to any symptoms suggesting minor illness during the preceding four weeks Of those found negative at the first examination none subsequently became carriers In three of the four families half or more of the household contacts were carriers, but in the family of case 3 specimens from all four members were consistently negative, moreover, one child in this family had no type 1 neutralising antibody in his serum Evidence of intrafamilial spread of infection was therefore lacking in this family Of all contacts from the four families there were eight children aged 1–10 years of whom six were virus carriers and nine adults of whom only two were virus carriers

Duration of excretion of virus in symptom free carriers—One of the eight symptom free carriers, an adult, was found to be carrying virus on the first examination only; in the remaining seven excretion was more or less prolonged one child excreted virus for 14 days, one adult for 31 days, four children for 48 days, and one child, aged 15 months, for 84 days

Examination of sewage—Type 1 poliomyelitis virus was found in sewage coming from parts of the town other than the houses of the cases, in the sampling both of Jan 19–21 and of March 16–18 This indicates the presence in the town of infected persons outside the families of cases, both at the beginning of the quarantine period and after it was over Virus was not found in the February and May samplings Type 1 poliomyelitis virus was also isolated from the swabs left in the drain of the house of case 4 in January and February, at which times four out of six and five out of seven persons respectively in the household were excreting the virus

Examination of school-children in Village B—One of the eighteen children at the village school was excreting type 1 poliomyelitis virus on March 2 but not on March 23, and thirteen out of the eighteen had type 1 neutralising antibody in their blood on both occasions None of the three quarantined contacts was excreting virus at the time of his or her return to school

Examination of water—Virus was not isolated from the samples of piped water of Town A and water from the deep bore hole in Village B

Discussion

This outbreak was favourable for observing the effects of quarantine measures, since it occurred in the winter with a small and easily observable number of clinically apparent infections and only one type of poliomyelitis virus, type 1, was concerned

Quarantine was applied to the families of the first four cases for 54 days, starting on the 5th day after notification of the first case and 12 days after the onset of the minor illness The restrictive measures conformed in general to those recommended by the World Health Organisation (1954) and by the Ministry of Health (1954) but their application lasted more than twice as long

In assessing the effects of quarantine measures it is important to take into account the fact that 47% of the household contacts were excreting virus when quarantine was applied There is no way of knowing whether the paralytic or the subclinical infections occurred first; moreover the dating of the outbreak from the onset of diagnosed poliomyelitis ignores possible preceding subclinical infections elsewhere in the community That this was in fact the case is suggested by the finding of virus in sewage from other households in the community during the first week of quarantine although type 1 virus had not been found at the sampling two months before the outbreak started A week after the raising of quarantine restrictions virus was again found in the sewage away from the cases' households The other community group outside of the cases' households that was studied was the school in Village B where five days before quarantine ceased one child was carrying type 1 virus and thirteen out of eighteen had serological evidence of infection at some time in the past with this virus It seems probable that infection had been travelling silently round the school during the time of the quarantine restrictions. Further evidence of the wide distribution of the virus is given by the occurrence of the fifth case from Village C four weeks after quarantine was started Thus, in spite of the restrictions on the contacts of the known cases, evidence was obtained of infection in the community during this period

The findings in the household contacts of the cases are of interest The proportion demonstrated to be infected with poliomyelitis virus *in the fæces* 8/17 (47%), is closely similar to that (41%) which has been found during outbreaks in the United States studied mainly by Francis and his colleagues (Brown et al 1954). The infection rate was much higher in the children than in the adults and the duration of excretion was longer in the children Only one out of the four households did not show evidence of intrafamilial spread In each of the families to show contact infection the youngest child showed the longest duration of excretion The *infant with its high susceptibility to infection* its liability to prolonged virus carriage and its untrained bowel habits provides both a rich source of virus and a ready means of dissemination into the household environment

The duration of excretion of virus by household contacts of cases of poliomyelitis does not appear to have been measured previously There were eight symptom free virus carriers in this group seven were still excreting virus 14 days after the first examination, six after 21 days five after 48 days and one aged 15 months, after 84 days. These durations of observed excretions probably do not represent the total period of virus carriage which may well have started before observations were begun Quarantine seems to be of doubtful value in practice if at the end of three weeks, three-quarters of the infected members are to be returned to the community still carrying virus Even when the period of quarantine was more than *doubled as for this study*, more than half the carriers were still infective at its termination

We conclude that the findings in the household contacts suggest that quarantine could not be an effective preventive measure in poliomyelitis and that the community studies show that in this instance spread of infection took place despite them

Summary

During a small outbreak of poliomyelitis in a country district in the winter months quarantine was applied to the households contacts of the first four cases for seven and half weeks.

Evidence *from virological studies is presented* showing that community infection took place despite the quarantine measures and the virus was found in sewage draining houses in which no clinical cases of poliomyelitis had occurred.

Eight out of seventeen household contacts of clinical cases of poliomyelitis due to type 1 virus developed infection without symptoms. 21 days after virus was first found six out of eight after 48 days five out of eight and after 84 days one out of eight were still carrying virus

It *seems* clear that under the conditions observed which were peculiarly favourable to the imposition of quarantine measures, infection was widely disseminated in the community and must have been spread by other means than by the patients and their immediate contacts.

We are grateful to the family doctors the sanitary inspectors of urban and rural districts, and the *medical officer of health* in the area concerned, as well as to the director of the Ipswich Public Health Laboratory all of whose collaboration made this investigation possible and to the Eli Lilly Fund, out of which the Spinco centrifuge was purchased

Poliomyelitis Vaccination

It is expected that mass immunisation of children against poliomyelitis in the United States will begin again shortly [1] In a statement on May 24 Dr Leonard A Scheele United States Surgeon General, said that " vaccine produced by all manufacturers has been proven to be safe except possibly the lots of Cutter vaccine Later he said that he expected Federal clearance for some vaccine early this week. The six manufacturers licensed to produce the vaccine have agreed to the government's proposals about safety standards, with '*more sensitive and more frequent*" testing of the vaccine

On May 27 the number of confirmed post-vaccination cases of poliomyelitis was 111

Control of London's Health Services

At a meeting on May 25 London Executive Council unanimously resolved that to transfer control of personal health services operated by the county council back to the borough councils would not be in the best interests of the population and ' in fact would be highly undesirable.'

The *executive council* had been invited by the county council to consider a proposal that certain health services should be transferred or delegated to the Metropolitan borough councils. At its meeting the council had before it a report by the local medical committee which also was unanimously opposed to such a change

In its report the committee remarked that since 1948, when London County Council took *over personal services from the boroughs*, much administrational duplication had been done away with The increased nursing staff now responsible for the whole of the child population had been integrated ; and the service was being " run with the utmost efficiency ' If responsibility were to be restored to the borough councils, the extent of some of the services would depend *entirely on the local rate* and those living in the poorer boroughs where the rates *are* highest would obviously suffer most ' It had been suggested that responsibility for the home health service should be divided between the county council and the borough councils but we have in the past seen the chaotic position of delegated responsibility in the tuberculosis service The committee observed that though it was proposed that the borough councils should *exclusively control the services* transferred to them, liaison between the boroughs was *to be* arranged to the satisfaction of the county council and this proposal was unworkable

In England Now

A Running Commentary by Peripatetic Correspondents

In our little town, local pride boasts of three claims to fame—its salubrious salts, its generous accommodation for the mentally afflicted, and its Derby. Up on the downs, the hygroscopic chemicals in the soil give the turf an invigorating springiness which seems to communicate itself to the race-goers, and for those with time for reflection there is always the magnificent view of the pinnacles of the great mental institutions. There is a theory, popularly held after a trying outpatient session, about the indifferent mental health enjoyed by a singularly large section of the local population. This claims that many ex-patients settle here and raise families, for even they are aware of the unique attributes of the district.

On Derby Day one receives the distinct impression that all three major industries combine to ensure its success. Red-hot tips issue forth like sparks from a furnace and many a credulous victim has cause for regret after the race. The afternoon's work necessarily ceases, and those with outpatient appointments are seized with a sudden, though temporary, zest for fresh air. Among inpatients, no-one is too ill to take an interest in the commentary, and preparations usually begin in the morning with a popular clamour for the famous salts, whose pharmacological effect is ideally calculated to relieve all concerned from distracting thoughts at an exciting moment later in the day.

This year proved no exception in that losses were many and winnings were few. An inevitable gloom descended on the wards, impoverished tendon reflexes and subnormal evening temperatures were common, and the prospect of a forthcoming election failed to lift the depression. The only optimism sprang from a few undesirable characters who presented themselves at the casualty door in the hope of a night's bath, board and lodging, and theirs was short-lived.

* * *

He was a welcome change from the succession of dreary souls with faces as long as their list of symptoms, and tempers as irritable as their colons, and my heart warmed to his cheery face and twinkling eye as he puffed in medical outpatients. My surgical colleagues had obviously felt the same way about him, for they hoped that we would relieve his bronchial spasm as successfully as they had his retention.

Having duly percussed and listened, I was about to prescribe an antispasmodic and an expectorant when it struck me that his G P might already be giving him something of the sort. To my question he replied that his doctor prescribed a medicine, three times a day; a small pill, twice a day; an inhalation, one a day; and a linctus for the night.

"And do they help you?" I asked, thwarted. "Oh, I don't ever take them," he replied. "But you won't write and tell him that will you? It might hurt his feelings. You see, he is a fine doctor, and I have great faith in him."

* * *

XYZ was a normal English village and I had settled down to a peaceful holiday locum, when, one sunny afternoon, the telephone rang.

"Hello. This is Dr B—Dr A is on holiday. Can I help you?"

"This is Miss C, Miss D, who keeps bees, has just had a nasty sting and seems to be having a general reaction this time. I have already given her 'Antistin' and I was wondering if I should give her calcium?"

Miss C and Miss D were unknown to me—I had not even been warned about them—and Miss C's pharmacological knowledge appalled me.

"Well, Miss C, I don't understand why you wish to give calcium?"

"She has a generalised pruritus, Dr."

The word "pruritus" tripping so easily off the tongue made me even more uneasy and so in retaliation I asked:

"But do you have a preparation of calcium that can be given parenterally? No. (Good lord she understands that!) Well, I doubt very much whether the chemist here will have any either. Why don't you bring her round to the surgery and I'll see what I can do?"

Before their arrival I consulted the available vade mecums and was a little more at ease when they appeared. Miss D was easily dealt with. She had a generalised urticaria. Her eyes were puffy and bleary and she was so obviously uncomfortable that I got down to giving her adrenaline subcutaneously. Miss C was the real problem. She was a slender middle-aged woman made mannish by closely cropped hair. Throughout, whilst thrusting her hands deep into the go to hell pockets of her jeans, she lectured me on the anti histamines—never one of my strong points. At last, finding the going rather heavy, I asked her where she had learnt so much about these drugs.

"Just after the war, I became the keeper of the anthropoid ape section of the Munchausen zoo and, for a time, we had an allergic ape." Then as a wistful afterthought: "They're very like humans, you know!"

* * *

The car gently came to a halt about midway between York and Tadcaster. The time was 1 A.M., the nearest all-night garage was in York. After some time I was joined by the driver of a heavy lorry who stopped to offer help as is the nature of his kind. His tank was nearly full of petrol, but the task of transference appeared to be insuperable. The problem clearly was one of syphonage, and, in a moment of inspiration, the means became clear. The attachment of the two rubber tubes of a stethoscope to opposite ends of one earpiece supplied a syphon of effective length. The transfer of two gallons of the precious fluid was quickly completed and my journey home resumed.

My stethoscope was described by the makers as a dual-purpose instrument, and this claim appears to be justified. Perhaps the story should be entitled The Effective Use of the Stethoscope in Modern Medical Practice.

* * *

Not "In England" and not all of it "Now". When I was a R.A.M.C. surgeon in Egypt in 1945 I had so persistent a pain in my left renal area that I had an X-ray done. This showed nothing abnormal. A few days later my wife wrote from Devonshire that there was a new X-ray machine in the practice where she worked as a radiographer and her colleagues had used her abdomen as the subject of its first trial. The excellent films obtained showed a large stone in her left kidney. After the removal of the stone our health remained good until some months ago when I began to suffer from lassitude, loss of concentration, insomnia, and an ache in the suboccipital region. This led to a keener interest in the merits of vitamin B, barbiturates, and dextro-amphetamine sulphate, but with scant improvement. My wife consulted a gynæcologist two days ago and her ovarian cyst is to be removed in a fortnight.

Should I be blamed for failing to recognise my symptoms earlier?

* * *

In our family the teaching of citizenship or civics is pursued opportunistically rather than by plan, our main theoretical principle being to satisfy the child's thirst for knowledge as it is manifested. A golden opportunity presented itself on Election Day while we swallowed a hasty breakfast in order to get to the polling station.

Our eight year-old daughter courteously divided her attention about equally between her food and the unprepared talk we gave on the Constitution and the principles of democratic government by election. Our degree of success can be judged by her sole question:

"And what do you get if you guess right?"

* * *

Our hospital is taking its share in the road-safety crusade. Where the ambulance charioteers swing round the mortuary bend on the drive, we are to have a new notice—"DEAD SLOW."

* * *

Overheard outside the hospital after visiting hour

"I'm afraid he's in a bad way. He's got blood pressure and high blood pressure—so they can't do much for him. If they treat one it upsets the other."

Letters to the Editor

CIVIL SERVICE MEDICAL APPOINTMENTS

SIR,—My attention has been drawn to a letter signed Toad Beneath the Harrow in your issue of May 14 Your correspondent appears to be taking the Civil Service Commission to task for including in their advertisements for medical-officer posts in the Civil Service the phrase 'promotion prospects."

These posts were in the basic grade and there are at present 382 such posts Above these are 133 posts in the more senior grades, which are normally filled by promotion There is also provision for ' special merit' promotion in their existing posts for medical officers whose qualifications and experience are exceptional

The argument that promotion prospects disappear if senior posts are not standing vacant at the time of advertisement is to say the least, unusual It does not appear to be accepted by other employers

Civil Service Commission,
London, W 1

W H FISHER
Secretary and Commissioner

CANCER

SIR,—I read with interest and some amusement the ingenious argument against cancer education put forward by Dr Hazel Baker in your issue of May 21 Since I did not suggest the operation or perform it on myself I can only conclude that she advises all her patients to refuse an operation if there is any chance of cancer being present. Can pessimism concerning the disease go further?

The difficulty about her suggestion, that patients who do not understand their symptoms will report to their doctor at once is the fact that so often they give themselves the wrong explanation and in many types of cancer they delay six months or over a year as is proved by statistics. It is only by cancer education and talking freely about cancer that man (or woman) will become a less frightened and more reasonable animal

Yorkshire Council of the
British Empire Cancer Campaign.

MALCOLM DONALDSON
Director of Cancer Survey

SIR —May we as psychiatrists, comment upon Mr Donaldson s interesting article of May 7? It seems necessary to draw a distinction between true cancer phobia and cancer apprehension, terms which we think should not be used synonymously Educated and well informed persons may suffer from irrational fears and the true phobic patient will not be substantially influenced by reassurance or education his basic problem is an emotional one with deep unconscious roots

Whether education will bring the cancer-apprehensive patient to the doctor any earlier is an open question Surveys in this field have in fact been carried out in America and there is evidence to suggest that educated and cancer-conscious people may delay considerably in seeking help in the case of suspicious symptoms and signs In particular Bacon et al [1] found that of 40 women with breast carcinoma 28 were deemed to have shown neglect in consulting their doctors These women were not of inferior intellect and the delay was particularly remarkable in that all had been reached by cancer education and had thought of cancer at once

We have no ready means of advising the cancer experts on how to bring the cancer-apprehensive patient earlier to medical consultation We suspect however that delay in seeking help may not necessarily be evidence of ignorance or lack of information though admittedly much needless fear does indeed exist about cancer Delay in many cases may be indicative of the individual s emotional make up and the way in which he handles the difficulties that arise in his life The more mature and responsible the individual the more readily and realistically will he face the situation frightening though it may be

In short the problem is as much an emotional as an intellectual one

LOW-LACTOSE MILK FOR CONGENITAL GALACTOSÆMIA

SIR —The essential need in the treatment of congenital galactosæmia is the exclusion of lactose and galactose from the diet For infants and children with this disease, the most important dietary requirement is a low lactose milk preparation In the treatment of cases in Great Britain Bray et al [1] have given 'Nutramigen' but this is an American preparation and both dollars and a special import licence are required in order to obtain supplies Cox and Pugh [2] prepared their own synthetic food the casein of which contained 1% of lactose

We wish to report our success in treating a child with galactosæmia with a low lactose synthetic milk powder, and to recommend this food to others for the treatment of such children Messrs Trufood tell us that this special milk powder is not yet available through the ordinary trade channels, but that it can be supplied by them through hospitals

The patient a boy was first admitted to the Birmingham Children s Hospital at three months of age. He was marasmic, weight 10 lb 2 oz. (birth weight 10 lb 7 oz) and he had an enlarged liver jaundice and impaired liver function His urine contained 3 2 g of galactose per 100 ml and paper chromatography showed the presence of galactose only A galactose-tolerance test was carried out after a feed containing 5 g of galactose with the following results: blood galactose fasting 10 5 two hours 180 seven hours 31 5 mg per 100 ml. urine galactose total 1 3 g in a six hour collection following the feed.

Until he was seven months old the child was treated with nutramigen and made good progress on this food He was then given Trufood low lactose milk and his progress has been maintained satisfactorily

The principal nutriments in the low lactose synthetic milk powder were casein (washed) glucose maltose dextrin, and coconut oil The washed casein was first dissolved in a solution of mineral salts. After adding the fat and carbohydrate the reaction was adjusted to neutrality and the preparation completed by homogenisation, pasteurisation and spray-drying The approximate percentage composition of the final powder was protein 22 fat 22 carbohydrate 51 (dextrin 22 maltose 10 glucose 10) salts and water 5

In all four different batches of synthetic food have now been given to our patient The lactose content of the washed casein incorporated into two of these batches was 0·04% and 0·13% respectively giving values of 9 and 28 mg lactose per 100 g final milk powder

On the last occasion of testing (age fourteen months) after an 8 oz (227 ml) feed of the special Trufood milk containing 2 8 mg lactose blood galactose levels were: fasting nil forty five min 18 ninety min. nil mg per 100 ml ; urine-galactose fasting 11 one two and three hours nil four hours 11 mg per 100 ml These results indicate that the small content of lactose in this milk preparation did not cause any accumulation of galactose in the blood or lead to appreciable galactosuria

The lactose contents of the washed casein preparations were determined by the method of Harding and Downs [3] in protein free filtrates obtained by an application of the zinc hydroxide (Somogyi) procedure Blood and urine galactose concentrations were determined by the same method [3] as described by King [4] for blood, and applied to urine filtrates prepared by the lead carbonate purification procedure of Dittebrandt et al.[5]

CARDIAC MASSAGE

SIR,—I have read with interest the article by Mr Neri and Mr Stevenson [1] The authors have brought out the advantages of their approach, which consists of an abdominal incision with subsequent splitting of the xiphoid process and blunt dissection of the sternal origin of the diaphragm through the foramina of Morgagni or "Larrey's spaces" The left pleura is subsequently opened and the whole hand is introduced into the chest

Although this may represent a "new approach" it differs little from the method used in 1902 by Porrier and even earlier by Mauclaire Wexler and Bromberg in 1951 described what they felt was a "new approach," in which the same anatomical dissection was made Subsequently Devine and Devine have introduced a somewhat similar technique Bost in the early 1920s described a similar procedure for exposing the heart In general, all of these approaches have similar disadvantages, which on occasion can be serious

After reviewing the records of over 1730 cases of cardiac arrest which have been sent to us, and which are included in our cardiac arrest registry, my associates Dr J William Hinton and Dr L Corsan Reid and I have concluded that the thoracic approach for cardiac "massage" is the method of choice for the following reasons

1 The transdiaphragmatic or other procedures initiated beneath the diaphragm, or other procedures initiated through the abdominal incision, do not display the heart directly as is possible with the thoracic approach By direct display the heart s activity can be assessed more accurately Ventricular fibrillation is not always recognisable by palpation, and therefore it would be more likely diagnosed by the direct approach

2 In about 15–20% of all cases ventricular fibrillation is present In such instances defibrillation is most reliably effected by the electrical defibrillator, and the thoracic exposure allows easy application of the electrodes

3 Drugs can be accurately injected in order to avoid the coronary vessels, and can be instilled into the heart-chamber for which they are intended

4 The pericardial sac may need to be opened and can be most easily approached through the thoracic route By such an approach the phrenic nerve is less likely to be severed We also believe that the proper closure of the pericardial sac is best accomplished through the thoracic approach

5 Manual massage through the thoracotomy incision results in more adequate cardiac output, and there is less chance of subsequent irreversible cerebral damage Clinical experience as well as repeated work on dogs has convinced us that proper massage should maintain a circulation only slightly below the normal level All experiments of which we are aware indicate that massage initiated through an abdominal incision does not bring about as great an output as does manual compression of the heart through the thoracic approach

6 It is often helpful to shunt additional blood to the brain and into the coronary circulation By the thoracic route the aortic can be pinched off with the fingers or with a rubber shod clamp just beyond the origin of the great vessels

The thoracic approach should be no less rapid than any other One need not be a thoracic surgeon to enter the intercostal space and expose the heart Artificial respiration must be maintained regardless of which route is used Neri and Stevenson describe their route as an avascular one, and it is quite possible that post resuscitative bleeding would be somewhat less, but the superior deep epigastric vessels pass through the space described In addition cardiac arrest often happens at times when aseptic technique cannot be followed, often one does not have time to put on gloves (Cardiac arrest is essentially a 3–4-minute emergency with few survivals after cerebral anoxia has persisted for more than 4 minutes) The approach described by Neri and Stevenson involves a risk of generalised peritonitis and also of empyema

It appears that in this country the thoracic approach is now used almost universally The survival rates are apparently greater with this route, many large medical centres have reported survival-rates of 60–80%

HUGH E STEPHENSON, Jr.

DRUGS IN THE TREATMENT OF DEPRESSION

SIR,—In your annotation of May 21 you draw attention to the large doses of methylamphetamine which I have reported,[1] greater than those often suggested Sargant and Slater,[2] for instance, give the daily dose of amphetamine as up to 20 mg, adding that half the dose of methylamphetamine gives the same effect

The maximum daily oral dose which I have used has varied considerably, whether given as a single dose or divided into three doses before 1 P M The table below shows the maximum daily dose given to every patient I have treated at the late Dr Elizabeth Casson's Mount Pleasant Nursing Home The effect of each dose has been recorded by day and night observation

Daily dose (mg)	*No of patients*	*Daily dose (mg)*	*No of patients*
1 25–5	45	17 5–20	21
7 5–10	34	22 5–30	29
12 5–15	30	32 5–40	13

2 patients received a maximum daily dose of 1 25 mg., but 8 received 45 mg and 1 60 mg

Methylamphetamine should be administered with care and no increase of dose greater than 2 5 mg should be made, and then only after full knowledge has been obtained of the effect of the previous dose Psychological disturbances and psychoses have been produced by daily doses of 50 mg of amphetamine [3] so that any dosage of methylamphetamine above 30 mg daily should be approached with special caution

Bristol.

G DE M RUDOLF

HARDENED FATS AND LUNG CANCER

SIR,—Professor Yudkin (May 14) claims that margarine contains essential fatty acids, although there can only be a question of one, linoleic, and, in comparing margarine with butter containing linoleic as well as arachidonic acid, he must have used the higher figures for linoleic acid content in margarine and a low average for butter He omits to mention arachidonic acid content although this acid has a high biopotency and appears to be the principal essential fatty acid to be supplied by the food or synthesised in the body from linolenic or linoleic acid

In comparing margarine with butter, undamaged vegetable oils, and animal fats I could have drawn attention to the fact that certain hardened fats accentuate fat-deficiency symptoms but, as this seems to be due to an increased essential fatty acid requirement, I thought it unnecessary at this stage to go further into this question

Lung cancer is increasing rapidly, rural lung cancer incidence is much lower than urban, and female lung cancer in most cases is about 22% of the male These features are reflected in our knowledge of the essential fatty acids the average consumption of the acids is decreasing rural produce (butter eggs, bacon &c.) is rich in the acids there is a sex difference in the requirement of these acids and for female rats it is 25% of that for the males

Copenhagen JOHAN F NYROP

SCHIZOPHRENIA OR GENETIC ENCEPHALOPATHY ?

SIR,—Adrian[1] and Murray[2] make clear that the brain can be grossly abnormal in the absence of microscopically demonstrable changes Penfield and Jasper[3] describe hallucinatory experiences many of which are typically "schizophrenic" except that they are episodic associated with epileptic foci in the temporal lobes, reproducible by stimulation and relieved by appropriate excisions Penfield and Jasper look upon the temporal lobes as the storehouses of rememberable experience The diagnosis of schizophrenia is not suggested by the total clinical picture: there are schizophrenic symptoms without psychosis.

The frontal lobes could hardly be responsible for less than is attributed to them by Penfield and Jasper—i e for planned initiative and the understanding of the future consequences of present action Jasper and Penfield state that stimulation of the frontal lobes does not produce the dramatic evidence of function revealed by stimulation of the temporal lobes but the fleeting distortion of planned initiative in a patient on an operating table would hardly be expected to do so although the same patient would soon run into trouble during the ordinary business of life if his planned initiative was distorted and his understanding of the future consequences of present action was seriously at fault Add some temporal hallucinations to such a patient and his perplexity and alarm are understandable Mental symptoms occur in the early stages of lesions in the "silent" areas,[4] and Miskolczy[5] suggested that the areas of the brain affected in schizophrenia are those which are typically human

The very considerable and convincing research on hypothalamic dysfunction in schizophrenia collected by Gellhorn[6,7] together with his own contributions, make it a reasonable proposition that in schizophrenia the lateral and posterior hypothalamus either is affected as part of the disease or is disordered by the disease (The lateral and posterior nuclei have developed throughout the mammalian series pari passu with the neocortex, both reaching the highest development in man[8]) Possibly both statements are true although I suggest that schizophrenia is more likely to produce autonomic changes than are autonomic changes to produce schizophrenia Anatomically[8] and physiologically[6,9] the functional integration between the cortex especially the frontal cortex and the diencephalon is so intimate that in the matter of nervous activity one is back with the hen and the egg At any rate add autonomic dysfunction to the frontal and temporal "paraesthesia" of the mind already suggested and the picture of schizophrenia is fairly complete

The evidence concerning heredity the early age at which schizophrenia develops, and the absence of any conclusive proof incriminating known pathogenic influences all suggest an inborn error producing ontogenetically inevitable pathology or pathology made manifest by factors not recognised at present to be pathogenic

The hypothesis is advanced that schizophrenia is a progressive disease process which throws regions of the brain into disorder and then out of action which spreads usually from the frontal poles backwards (although it may start in the temporal lobes or in the hypothalamus) and which spreads in tidal fashion with periodic recessions during any one of which the disease may become arrested It is further suggested that schizophrenia would be better known as phylogenetically and ontogenetically determined encephalopathy (the shortened term "genetic encephalopathy" would probably cause no difficulty despite other genetic encephalopathies)

If this hypothesis stands then:

(1) The disease must be unknown in animals and in very young children.

(2) Depending on the area first or mainly affected there would be indeterminate types

(3) Dysfunction in the hypothalamus would produce pituitary, suprarenal thyroid, and sex gland disturbances without actual disease in those structures.

(4) The early symptoms would be due to active disorder in brain cells, with dramatic symptomatology giving way more and more to loss of function and a form of mental defect. As a corollary "cures" of schizophrenia could result only in a level of human achievement which was less than that which might have been expected from early promise

(5) The electro-encephalogram would reveal atypical abnormalities, varying with the stage of the disease

(6) Patients with active disturbance could be helped by the removal or destruction in situ of parts disturbed

(7) However selective the toxin which imitates schizophrenia in its action, it would produce in addition effects on other parts of the brain, with more vivid and elementary hallucinations motor and sensory changes and disturbances of consciousness tending towards coma which are not observed in schizophrenia. Moreover such toxins would be most harmful to acute schizophrenics but cause less than normal disturbance in chronic schizophrenics.

CHLORPROMAZINE

SIR,—Dr Vaughan and his colleagues (May 28) state that chlorpromazine is not a curative drug but this does not detract from its value as a "special" sedative and resocialising agent

Chlorpromazine is clearly more successful than dummy tablets but I feel it must also be controlled against drugs producing equivalent sedative effects before the word "special," as a description of its effect can be justified. Until this has been proved chlorpromazine should not be allowed to supplant the much less toxic cheaper sedatives in common use

It would be interesting to know if other methods of resocialisation had been used in the treated patients, such as nursing in groups with a total daily programme

I feel there is a danger of reverting to the massive sedation of chronic patients with even more toxic drugs and the recent advances in nursing techniques which depend upon an unsedated patient are in danger of being overlooked

Hill End Hospital
St. Albans G I TEWFIK

OCCLUDING FOLEY CATHETERS

SIR —Various forms of clips and clamps are used to occlude the inflating tube of Foley catheters Many of these devices are crude and heavy and cause permanent damage to the tube

A simple and effective method—for which no originality is claimed—makes use of a circular disc of thin tin plate or aluminium approximately 1¼ in. in diam tops of certain brands of intravenous litre flasks lise is bent to about a right-angle across its di tube is laid in the broad groove thus fo is then inflated and the disc is briskly the diameter in which the tube lies, and to this The whole forms a quarter-circle

The side tube is thereby firmly occlu sm is light in weight and will not

The cost is nothing I have never known the method to fail in securing and maintaining the inflation of the bulb Nor does it damage the delicate rubber tube

Royal United Hospital,
Bath
A T MATHESON

RESEARCH AND THE PATIENT

SIR,—Professor Witts (May 28) does Birmingham an injustice in implying that William Withering lived at Edgbaston Hall and established the use of digitalis "before the establishment of a hospital in Birmingham"

The hospital I have the honour to serve is the successor of the Birmingham Infirmary established under the Poor Law in 1740, and of high repute in Withering's time The General Hospital, Birmingham, was established in 1765, although not opened until 1779, Withering was one of the four original physicians

Withering settled in Birmingham in 1775 and began his ten years' research on the foxglove His earlier patients he saw at his consulting-rooms in Temple Row, and his later ones in the Square It is most unlikely that he ever saw patients (except in emergency) at Edgbaston Hall, and in any case he only moved into the hall a year after the publication of *An Account of the Foxglove* in 1785

Thus two hospitals had been established in Birmingham before Withering began his research, and he was on the staff of one of them while he was completing the research

Summerfield Hospital,
Birmingham, 18
ROBERT J HETHERINGTON

LUNG CANCER AND SMOKING

SIR,—I notice that in the investigations into the relation between tobacco smoking and cancer of the lung, research-workers generally expose animals to tobacco fumes or paint chemicals contained in tobacco on the skin There is also a lot of discussion about the compounds which may be vaporised and inhaled at the temperature of a lighted cigarette

Has anyone considered the possible importance of inhaled fragments of cigarette tobacco? The customary method of inhalation will on occasions carry a piece of tobacco down the respiratory tract Most smokers have at times experienced this, and small pieces would perhaps stay for long periods in contact with respiratory epithelium. Such events, if they occur by chance, would be more common in heavy smokers, and would not occur when an efficient filter is used. The insufflation of minute pieces of cigarette tobacco into the lungs of mice might be a profitable experiment

Virus Research Institute,
Entebbe, Uganda
CEDRIC MIMS

SIR,—The recent claim that there is a definite association between lung cancer and smoking in males raises the whole question of the validity of certain statistical techniques used in these inquiries I refer especially to the indiscriminate application of the χ^2 test and equal samples to statistical data

It is generally agreed that the χ^2 test is only applicable in a normal or nearly normal distribution with a well-defined tail at each end, yet in these investigations it has been used in what is a distribution of Poisson type and where a large sample is necessary before a tail will emerge to the right

The proportion of smokers among middle-aged men in the U S.A. is about 90%, and in England and Wales about 95%[1] In 1952 the number of male lung cancer deaths was 11,981, mainly among men of 30 and over, numbering 11,857,000 If an average expectation of life of 15 years be assumed for a lung cancer case we therefore obtain a prevalence (case-rate) of 1 5% for this disease There is reason to believe, however, that the lung cancer population in the male community is as low as 0 2%

Denoting by S and C the presence of the attributes smoking and lung cancer, and by s and c their absence respectively, in the male population, the following 2 × 2 table results, where p_1 and p_2 represent the probability of smoking and lung cancer respectively

	C	c	
S	x		Np_1
s			
	Np_2		N

Np_1 and Np_2 are the average number of smokers and lung cancer cases expected in a representative sample N of males and x is the number of smokers with lung cancer (CS) occurring in the top left hand cell

Np_1 is much greater than Np_2 and x can range from 0 to Np_2 The expected value of x on the basis of non association between S and C is $Np_1\,p_2$ which is close to the maximum value of x possible, namely Np_2

Given x Np_1, Np_2 in the sample N the values in the remaining 3 cells are obtained by differencing

Denoting the probability of a value x occurring, assuming no association between S and C, by Px, the probability curve of the distribution over the whole possible range of x is obtained from the formula

$$Px = \frac{(Np_1)!\,(Np_2)!\,(Nq_1)!\,(Nq_2)!}{(N)!\,(x)!\,(Np_1-x)!\,(Np_2-x)!\,(Nq_2-Np_1+x)!}$$

As an example, taking N = 1000 p_1 = 90, p_2 = 015 we g Np_1 = 900, Np_2 = 15 The expected value of x is $Np_1\,p_2$ = 13 5

x	Px
0	0000
7	0000
8	0002
9	0018
10	0100
11	0421
12	1287
13	2692
14	3445
15	2035
	1 0000

It is seen that low values of x are very improbable and the range within which x occurs according to chance is $N\bar{p} \pm \sqrt{N\bar{p}\bar{q}} = 13\ 5 \pm 3\ 5$ or 10—1 within which the maximum value of x possible—i e, 15—lies The χ^2 test could not be applied here as no tail exists to the right. For a tail to emerge Np_2 would have to be greater than 810 or N greater than 53,300

In testing the significance of the association between two attributes in a universe their respective frequencies must be considered This is quite a different problem to that of testing for the significance between the frequencies of a given attribute in two different and independent communities As an example of the first problem we have the association between smoking and lung cancer and of the second, a comparison of the incidence of dysentery, say, in London and Manchester Equal sampling can only be used in the latter type of problem

The 2 × 2 table of Dr Doll and Professor Bradford Hill[2] is an artificial one and not a random sample of the male universe It is so distorted as to form a veritable strait jacket for x, the possible range being 1289-1357, only 5% of the lung-cancer cases The distribution is the normal type with a tail at each end As would be expected the χ^2 test gives high significance

Assuming, for example, that the lung-cancer frequency is 1 5% the probability of obtaining equal numbers of C and c is $\frac{(2714)!\,(0\ 985)^{1357}\,(0\ 015)^{1357}}{(1357)!\,(1357)!}$ which is so improbable as to be impossible ($\log P < -1570$) The test is thus meaningless and leads to a false conclusion

According to the samples, the proportion of smokers among males is 97 5% and among non lung cancer cases 95·5%

	C	c	
S	1350	1296	2646
s	7	61	68
	1357	1357	2714

The number of lung-cancer cases is Np_2 = 1357 and, assuming p_2 = 0 015, these would be expected from a male sample N=90,467 The expected number of lung cancer cases among this sample of males would be 90467 (0 015) (0 975) = 1323 The maximum value of CS cases possible, namely 1357, lies within the range $1323 \pm \sqrt{1323}$, or 1287 — 1359, and therefore well within the range of values due to chance selection. So that if all 1357 lung cancer cases were smokers the fact would not be significant

The following table gives the minimum values for samples necessary for a tail to emerge to the right of the probability curve

p_1	p_2	Np_2	N
0 950	0 015	3370	224,670
0 955	0 015	4190	279,300
0 975	0 015	13850	922,300
0 950	0 002	3420	1,710,000
0 955	0 002	4250	2,125,000
0 975	0 002	14040	7,020,000

It is seen that in order to be able to apply the χ^2 test for significance, *assuming the proportion of male smokers* to be 97 5% a sample of at least 14,000 lung-cancer cases would be needed If the proportion of smokers however is taken to be 95% the least sample required is 3400

---

[1] *Lancet*, 1952 ii 668

[2] *Brit med J* 1952, ii, 1271

To sum up, because of the high frequency of smoking and low frequency of lung cancer among males a greater proportion of smokers in lung-cancer males than among other males is to be expected and larger samples are required than those taken in order to show whether this is statistically significant moreover, the technique of equal samples in such an investigation is inadmissible Incidentally, it is difficult to see how an attribute with a high frequency like smoking can be the cause of a low frequency attribute like lung cancer

Bromley Kent. C A. GOULD

ELECTROPHORESIS OF PLASMA-PROTEINS

SIR,—From Dr Owen's letter of April 23 I understand that he is able to separate two components of the β-globulin fraction of the human serum by using paper electrophoresis He does not mention the time factor and the electric potential necessary to split the β globulin into its two components. This gives me an occasion to quote Wiedermann's paper,[1] describing a method of separation which I have confirmed in many cases[2] If the electrophoresis is performed in a wet tank (with 5-volt-per-cm filter paper a 'Veronal' Na HCl buffer, pH = 8·6 I = 0·05) not for the usual 8–10 hours but for 16–20 hours the β globulin falls into two components If the separation is continued for 20–24 hours the γ globulin will also separate into two components. Using a more alkaline buffer (pH 9–9 6) the separation becomes faster

Laboratory of the
Pediatric Clinic no II
University of Budapest. M. MILTÉNYI.

POTASSIUM DEFICIENCY AND KWASHIORKOR

SIR,—Hansen and Brock[3] reported that potassium retention exceeded the theoretical potassium/nitrogen ratio of 1/3 in 6 children admitted with diarrhœa, œdema and hypo albuminæmia All these children had hypokalæmia and in 2 treatment with a mixture of sodium and potassium salts alone was accompanied by electrolyte shift and loss of œdema They were careful to point out that all the children had œdema and diarrhœa while only some of them presented the other signs usually associated with the term kwashiorkor They may well be right in suggesting that electrolyte imbalance is important in the pathogenesis of nutritional œdema of the type they describe I am sure they would not claim from their experience in 2 children that it is the only factor involved in all such cases.

Heller and Schnieden[4] have shown that normal serum potassium levels may be found in children with kwashiorkor in Uganda These children all had œdema hypoalbuminæmia, and changes in colour and texture of the hair and/or skin Diarrhœa is a common but by no means universal feature of kwashiorkor as seen in the Kampala area of Uganda (it is probably less common here than in South Africa) Heller and Schnieden mentioned that severe diarrhœa was not a feature of the cases they investigated While agreeing with them that hypokalæmia is not an intrinsic feature of kwashiorkor in this area I should like to point out that potassium deficiency (which may exist in the presence of a normal serum potassium level) may be an important complication in cases with severe diarrhœa It may arise during treatment of children who have a normal serum potassium level on admission

It has been stated[5] that the diagnosis of potassium deficiency should be based on the existence of conditions predisposing to potassium loss In kwashiorkor with diarrhœa such conditions certainly exist and may be aggravated by high protein feeding after admission to hospital. The clinical diagnosis of potassium deficiency is particularly difficult in kwashiorkor since anorexia, diarrhœa, weakness, and less commonly vomiting are also features of uncomplicated kwashiorkor

Recurrence of anorexia specially if associated with vomiting abdominal distension, and weakness in a child with past or present diarrhœa, should I think make one suspect potassium deficiency Before this was recognised 9 out of 13 children presenting this picture went progressively downhill and died It is significant that 6 who received intravenous saline and glucose all died

Since the introduction of subcutaneous potassium therapy only 6 out of 15 such children have died Of these 2 had other severe complications, and only very limited potassium therapy was given to the other 4 Unfortunately many of the earlier children had to be treated without the serum potassium being examined Later estimations of serum potassium were made by the method of King[6] with the following results

	No of children	*Serum-potassium (m.eq per litre)*	
		Mean	*Range*
Children without kwashiorkor or diarrhœa	6	4 7	4 0–6 1
Kwashiorkor:			
No diarrhœa on admission	3	5 7	5 4–6 4
Diarrhœa on admission	7	4·0	3 1–5·6
Kwashiorkor with clinical potassium deficiency	4	2·6	1 6–3 5
On recovery	2	5 8	5 7–5 9

* 2 of these children had normal serum potassium on admission

Electrocardiographic signs were also non specific and cardiograms were not always obtainable. In 9 children with suspected potassium deficiency long P–R intervals (more than 0·14 sec) were found in half and flat T waves in all. There was no œdema of the chest wall when these tracings were made In 5 cardiograms were repeated during recovery although improvement was not dramatic all the cardiograms became normal except for one P–R interval which, although shorter was still outside the normal limit. QT was measured by several methods. The results were so variable even in the same cardiogram that no significance could be attached to the measurement

With this supporting evidence, replacement therapy was more energetically pursued, and children admitted with a history of diarrhœa, or who got diarrhœa later, are now given prophylactic potassium chloride (1 0 g daily) by mouth Children with subclinical deficiencies probably receive sufficient potassium in their milk to overcome their deficit.

Absolute evidence of potassium deficiency can be obtained only by dramatic response to intravenous therapy or by the demonstration of excessive retention by balance technique as used by Hansen and Brock. In view of the dangers of potassium intoxication it was considered wiser to rely on gradual replacement in these cases. Although the therapeutic response was gradual and therefore not diagnostic, the contrast with the fate of earlier children presenting a similar picture and not receiving potassium was striking In 2 cases serial cardiograms and serum potassium levels showed parallel gradual improvement

My regret that these findings are too few and not specific enough for detailed publication is mitigated by the fact that I have had no further cases presenting with severe potassium deficiency.

I am indebted to Prof A. W Williams for his interest and help in interpreting the cardiograms and to Miss M Lyle for some of the potassium estimations.

Medicine and the Law

Inspection of Surgery

THE London Executive Council dealt last week with the case of a doctor who refused to permit the inspection of his surgery Clause 7 (5) of the N H S Terms of Service requires that a doctor shall permit the inspection of his surgery by a duly authorised member or officer of the local executive council

In March, 1955, the chairman of the London Executive Council directed that the surgery of Dr X should be inspected, and the practitioner was asked to state convenient dates and times Dr X wrote stating that he occupied a small flat part of which was used as a consulting room and living room, he was not prepared to allow any intrusion into his private dwelling and, as he had only a small list of patients, the question of inadequate waiting room accommodation did not arise Dr X further stated that, if his surgery was detached from his private dwelling, he would have no objection to an inspection provided it were carried out by an official other than a doctor, but his search for larger premises had been unsuccessful

Dr X was asked to attend before the medical service committee, but he replied that he was still unwilling to allow an inspection of his surgery to be made and that he did not propose to attend the meeting

The council decided to make representations to the Minister of Health that the sum of 5 guineas be withheld from Dr X's remuneration Dr X has twenty eight days in which to appeal

Notes and News

WORLD HEALTH ASSEMBLY

AT the World Health Assembly in Mexico City last week, it was decided to expand the World Health Organisation's anti poliomyelitis programme Previous plans have included the setting up of a network of poliomyelitis laboratories in recent months to study the different strains of virus identified in each participating country, as well as other viruses responsible for diseases similar to poliomyelitis These laboratories are also studying the epidemiology of the disease and are making surveys of the natural immunity in different populations Two further tasks will now be undertaken the preparation and distribution of standard laboratory reagents in order to facilitate the work of national poliomyelitis centres, and the training of virus specialists in new tissue culture techniques used in this work A resolution was adopted to establish a world wide fund to assist national programmes for the eradication of malaria The fund, which would be fed by voluntary contributions from government and private sources, would be administered by W.H O The new fund would be devoted to the provision of supplies, equipment, and services to those governments whose needs could not be met through W H O's regular and technical assistance budgets

APPROVED NAMES FOR DRUGS

THE British Pharmacopœia Commission has issued the following new supplementary list of approved names

Approved name	*Other names*
Chlorhexidine	Bis *p*-chlorophenyldiguanidohexane Hibitane
Diethylthiambutene*	3 Diethylamino 1 1-di 2 thienylbut-1 ene Themalon
Dimethylthiambutene*	3 Dimethylamino 1 1-di 2 thienyl but 1 ene
Ethylmethylthiambutene*	3 Ethylmethylamino 1 1 di 2 thienylbut 1 ene
Methyl Phenidate	Methyl 1 phenyl 2 piperidylacetate Ritalin is the hydrochloride
Phenindione†	2 Phenylindane 1 3 dione Phenylindanedione Dindevan
Polymyxin	Antimicrobial substances produced by *Bacillus polymyxa* (Specific substances are designated by a terminal letter thus, Polymyxin E)
Streptonicozid	A compound formed by interaction of a suitable streptomycin salt and isoniazid Streptohydrazid
Triprolidine	*trans* 1 2' Pyridyl 3 pyrrolidino-1 *p*-tolylprop 1-ene Actidil is the hydrochloride

* Not intended for use in human medicine, diethylthiambutene is of interest in veterinary medicine

† Replaces phenylindanedione as the approved name

N.H S ACCOUNTS

FEW doctors, at the form filling end, would suggest that the National Health Service's methods of book keeping are lax and inadequate But the Comptroller and Auditor General in his annual survey of the N.H S accounts 1953–54 for England and Wales [1] and Scotland [2] once more politely voices the professional's slightly pained surprise at the amateur's apparent indifference to accounting niceties Thus he relates with approval that the Ministry of Health has drawn the attention of hospital authorities to his plea for the "normal system of competitive tendering for supplies,' but adds with distress that some hospitals still have not adopted or fully adopted the system One group of teaching hospitals who have for five years been refusing to interfere with house committee policy, have indeed agreed to reconsider the possibility of centralised group purchasing, but firmly add that "they would not expect more centralisation to result in better control of expenditure '

Again some hospital authorities have not yet completed the financial arrangements for the provision of medical services to local authorities, which the Ministry recommended at the beginning of 1953 Nor do the local authorities appear to have been coöperative Some have resisted claims made by hospital authorities, and owing to "difficulties of apportionment" some £122,000 for the period up to March 31, 1952 is still outstanding in the accounts of the Welsh regional hospital board.

---

[1] H M Stationery Office 1955 Pp 41 2*s*

[2] H.M Stationery Office 1955 Pp 26 1*s* 6*d*.

The Comptroller in both reports refers severely to losses by fraud. Cashiers who take no annual leave and keys that are kept on tops of cupboards are in his view inconsistent with "normal accounting prudence Disciplinary action and inventories of stores also seem to him to show certain weaknesses.

Among his polite admonishments he has included some interesting facts. At Dec 31 1953 of the 1728 full time and 4684 part time consultants in England and Wales 2175 (33 9%) were receiving distinction awards, but the Ministry did not know the total cost nor how many awards went to full time and how many to part time consultants. Scotland is better informed and on March 31 1954 when there were 401 full time and 395 part time consultants, 74 (18 5%) full time and 140 (37 7%) part-time consultants were receiving awards of which the total cost was £220 408

The Comptroller also gives figures showing that the expenditure on compensation to hospital patients has risen from £23,636 in 1949–50 to £159 047 in 1953–54 The number of cases has risen from 507 to 1100 He points out that judgments in 1951 and 1954 have extended the hospitals liability until it now covers the whole of their staff "whether permanent or temporary resident or visiting full time or part time."

IRRADIATED BUTTERFLIES

An increased incidence of abnormally marked butterflies was reported from Japan after the atomic explosion at Nagasaki So Mr E M Elmhurst F.R.C.S of Ipswich, has been dosing caterpillars and pupæ of the Large Cabbage White Butterfly (*Pieris brassicæ*) with 200–1000r of X rays with a view to finding out if irradiation affects the distribution of pigment. The effects observed in human beings subjected to X rays are contradictory some skins darken others become paler The black areas on the wings of *P brassicæ* are due to the same pigment as is found in man—melanin Mr Elmhirst's results so far have been rather puzzling some butterflies appear normally pigmented but emerge from the chrysalis minus some of their legs or with broken antennæ. The greatest change in pigmentation has been a butterfly with grey instead of black patches on the wings but presumably this butterfly belongs to the spring or early summer brood and normally all the "black patches in this brood are grey—it is only the late-summer brood that has really black patches.

Genetic changes are also being studied and Mr Elmhirst has reached the third generation of inbred irradiated butterflies. The difficulty however in getting them to breed in captivity has led him to free them after staining the outer parts of the upper and lower surfaces of both fore and hind wings bright red with mercurochrome Anybody seeing any such *P brassicæ* is requested not to kill the butterfly but to let Mr Elmhirst know at Trophy House Grimwade Street Ipswich Suffolk, so that he can try to find their progeny About 170 have been freed and more are to follow Most of the reports of sightings come from the country to the west of Ipswich especially the vicinity of Colchester and Braintree; but one insect was sighted at Shoeburyness, and others have been reported from nearer London. This is not surprising for *P brassicæ* is famous as a migrant and usually travels westwards.

University of London

The title of professor of morbid anatomy in the university has been conferred on Dr C V Harrison in respect of his post at the Postgraduate Medical School of London.

Dr Harrison who at present holds the appointment of reader in morbid anatomy at the school studied medicine at Cardiff and at University College, London In 1929 he took the B.SC and M.B. of the University of Wales and the University of London After holding a house-appointment at the Cardiff Royal Infirmary he became assistant lecturer in pathology at the Welsh National School of Medicine In 1938 he took the M.D Lond Later he became senior lecturer in pathology in the University of Liverpool. His published work includes papers on sympathectomy in arterial disease and hypertensive and ischæmic heart-disease

At a recent examination for the academic postgraduate diploma in psychological medicine the following were successful:

R W A C Barton R H Gosling L A Hersov

University of Sheffield

Dr Margaret Middleton has been appointed clinical teacher in child health and Mr N W Reece honorary demonstrator in surgery

University of Edinburgh

Dr J H F Brotherston has been appointed to the chair of public health and social medicine in succession to Prof F A E Crew F.R.S who retires on Sept. 30

Dr Brotherston graduated M.B. from the University of Edinburgh in 1940 After holding house-appointments in Edinburgh he served with the R.A.M.C from 1941 to 1946 He spent the next year at the London School of Hygiene and Tropical Medicine when he held a Rockefeller fellowship in public health In 1948 he was appointed joint lecturer in social and preventive medicine to the school and to Guy's Hospital Medical School In 1949 he was given leave of absence to work, with a Rockefeller fellowship at Johns Hopkins University School of Hygiene and Pittsburgh University Graduate School of Public Health He was also a consultant to the United States Public Health Service. In 1951 he became senior lecturer in public health at the London School of Hygiene and for a year he was also part time divisional medical officer in south west Hertfordshire Two years ago he was appointed to the readership in public health at the school In 1952 he published a monograph on the early public health movement in Scotland

Royal Australasian College of Physicians

The following having satisfied the board of censors in Australia have been admitted to membership

D T Church B D Cotton A W T Edwards D A Ferguson R A B Holland R G Lewis D C Maddison R S Packard R D Spooner Claire Weekes (New South Wales) Peter Ebeling K F Fairley W S C Hare K H McLean, B W Neal J S Penington (Victoria) T M Ferrier (Queensland)

The following having satisfied the board of censors in New Zealand have been admitted to membership

W M W Brookfield R H Culpan P W Dykes G F Hall R W Hornabrook J D McGregor, J R Presland, D H H Pullon, F T Shannon C M Stubbs J M Tweed M H Watson R D Wigley

Faculty of Ophthalmologists

The following have been elected officers for 1955–56

President, Dr John Marshall, vice presidents, Mr T Keith Lyle Mr J R Wheeler, hon treasurer Mr A McKie Reid hon secretary Mr E F King

Beit Fellowships for Medical Research

The following elections have been made to junior fellowships (£800 a year):

P C Caldwell M.A., D PHIL. Oxfd To investigate the mechanism of muscular contraction in crustacea at the Marine Biological Laboratory Plymouth

R H Côté B.A B.APP.SC, D.SC, Laval Quebec. To investigate the chemical constitution of human blood-group substances of the A B and O Lewis systems, at the Lister Institute of Preventive Medicine London

Miss E I B Dresel M.A PH D Camb To investigate the biosynthesis of porphyrin pigments at University College Hospital Medical School, London

J M Lowenstein B.SC Edin PH D Lond To investigate the biosynthesis of pyrimidines in mammals at the department of biochemistry University of Oxford

R Whittam, B.TECH.SC Manc. D PHIL. Sheff To investigate the metabolism of adenine nucleotides in relation to the active transport of inorganic ions at the Physiological Laboratory University of Cambridge.

Little Committee for the Study of the Infantile Cerebral Palsies

A century after the publication of Little's classical descriptions of cerebral palsy this committee has been formed to study the clinical problems of diagnosis prognosis, and management and the administrative problems of training medical and other personnel for work on cerebral palsy The members are

Dr W R F Collis (chairman) Mrs Eirene Collis Dr William Dunham Dr L T Hilliard, Sir Francis Walshe F.R.S., and Dr David Lawson (secretary) Dr Lawson's address is Queen Mary's Hospital for Children Carshalton Surrey

Commonwealth Bursaries

The latest awards under the Royal Society and Nuffield Foundation Commonwealth bursaries scheme include the following

To Dr A A Kinnear Institute for Pathology, University of Pretoria, to enable him to study endocrinological techniques at Birmingham

To Dr J H D Millar consulting neurologist, Royal Victoria Hospital Belfast to enable him to study electrocorticography at the Montreal Neurological Institute

This is the third group of awards under the scheme instituted in 1953 to provide facilities for increasing the efficiency of scientists of proven ability by enabling them to pursue research learn techniques, or follow other *forms of study* in natural science in countries other than their own in the Commonwealth where the physical or personal environment are peculiarly favourable

Deutsche medizinische Wochenschrift

Original articles in this journal are now followed by summaries in English and Spanish.

Society for the Study of Fertility

This society is to hold a conference in Birmingham on June 23 and 24 Further particulars may be had from Mr H H Fouracre Barns, 31, Weymouth Street, London, W 1

Middlesex Hospital Medical School

Prof Corneille Heymans (Ghent) will give a lecture on the History of the Development of our Knowledge of the Physiology of the Baroceptors and Chemoceptors, on Tuesday, June 7, at 4 30 P M , in the medical school

Pembury Hospital, Kent

Two stained glass windows were dedicated by Bishop J C Mann in Pembury Hospital Chapel on May 22 to the memory of F Carter Browne and E C Hughes, surgeons to the hospital, and also of Amelia Scott, a social worker

Cambridge Graduates' Medical Club

The annual general meeting and dinner this year will be held at Jesus College on Friday, June 24 Members of the club who have not received a notice, or who have not yet notified their intention to be present, should communicate with Dr T B Anderson, 1, Huntingdon Road, Cambridge

International Congress on Diabetes

The second congress of the International Diabetes Federation is to be held at Cambridge from July 4 to 8, under the presidency of Sir Lionel Whitby On July 4 Dr Elliott P Joslin will deliver the Banting lecture of the British Diabetic Association He has chosen as his subject Diabetes for the Diabetics Further information may be had from the office of the congress, 152, Harley Street, London, W 1

Symposium on Stammering

The Goldsmiths' College announce a public symposium on stammering to be given on Monday, June 20, by students of Mr H V Hemery's speech re-education classes for stammerers. Of the three assistant chairmen, two will be members of the medical profession The meeting will be in the small concert hall of the college, New Cross, London, S E 14, and will begin at 6 45 P M

Royal Society of Tropical Medicine and Hygiene

The society's annual meeting will be held at Manson House, 26, Portland Place, London, W 1, on Wednesday, June 15, at 7 30 P M , when Prof R M. Gordon will be inducted as the new president Afterwards, to mark the centenary of the birth of Sir David Bruce, Sir William MacArthur will give an address entitled an Account of Some of Sir David Bruce's Researches, Based on his own Manuscript Notes

Postgraduate Medical School of London and Hammersmith Hospital

The school's 20th anniversary and the hospital's jubilee are to be celebrated next week On Monday, June 6, the Queen is to visit the hospital Wednesday, June 8, will be an Open Day, from 2 30 to 5 30 P M , when there will be an exhibition illustrating the school's research work, and doctors will be able to see a programme of medical films in the lower lecture theatre

Radioactive Materials in Biological Assay

This subject is to be discussed at a joint meeting of the biological and physical methods groups and the Scottish section of the Society for Analytical Chemistry with the Edinburgh and East of Scotland sections of the Royal Institute of Chemistry, the Society of Chemical Industry, and the Chemical Society on Monday and Tuesday, July 11 and 12, in the department of biochemistry, University New Buildings, Teviot Place, Edinburgh.

British Association of Urological Surgeons

This association is to hold its annual meeting from June 30 to July 2 at the Royal College of Surgeons of England, Lincoln's Inn Fields, London, W C 2, under the presidency of Mr Terence Millin The programme includes a discussion on Calcification and Calculus Formation in the Upper Urinary Tract, and at a joint session with the section of urology of the Royal Society of Medicine The subject is to be the Treatment of the Paraplegic Bladder

Medical Golfing Society

In the society's summer meeting at the Berkshire Golf Club, Ascot, on May 26, Dr J G H. McNabb won the *Lancet* cup (scratch medal 78) and the Henry Morris cup (2 up)

Inauguration of an Accident Service

From June 1 the Royal National Orthopædic Hospital, Brockley Hill, Stanmore (Grimsdyke 2900), is operating a twenty four hour accident service for the treatment of orthopædic injuries There are facilities for the reception of injured direct from the site of the accident Requests for admission or outpatient treatment should be made to the duty registrar

Investigation of Tonsillectomy

The South East Metropolitan Regional Hospital Board has approved plans for an inquiry into the value of tonsillectomy (*Times*, May 26) At Farnborough Hospital, Kent, and perhaps other hospitals in that area, 1000 children on the tonsils waiting-list will be chosen for the trial 500 will have their tonsils removed and 500 will not The health of the two groups in the succeeding year will then be compared.

Dr J Ferguson Smith has been elected an honorary member of the German Dermatological Society

Dr K. G Bergin British Overseas Airways Corporation's medical superintendent at London Airport has been elected a fellow of the Royal Aeronautical Society

Copies of the report on pre war diets, the subject of a note in our issue of May 21 have been sent to public libraries The Carnegie United Kingdom Trust has only a limited number of copies for further distribution

New British standards include a glossary of terms used in radiology (B.S 2597/1955, price 10*s*) and a standard for electrically heated blankets (B.S 2612/1955, price 3*s*) Copies are obtainable from the Sales Branch, British Standards Institution, 2, Park Street, London, W 1

Births, Marriages, and Deaths

DEATHS

BUCKLEY —On May 28 Charles William Buckley, M.D , F R.C.P., of Bentley Corner Ashbourne, and formerly of Buxton, in his 81st year

RESPIRATORY INSUFFICIENCY*

A C DORNHORST
M.D Lond F R.C P
READER IN MEDICINE ST THOMAS'S HOSPITAL MEDICAL SCHOOL, LONDON

I HAVE chosen respiratory insufficiency as my subject because it is a common and important condition which is inadequately dealt with in most textbooks Moreover there has been in the last few years a good deal of work on disordered respiratory physiology It will be my purpose to show that this work although it has not ...sued in any dramatic therapeutic advance may be made to help in our everyday clinical tasks of recognising ...ssifying and assessing disorders

* * *

I should like to illustrate this by three very ordinary cases.

The first patient was a man of 45 who complained of ...ertional dyspnoea first noticed fifteen years previously and becoming steadily worse He had had no cough until ...r years previously, and had since had sputum only intermittently Physical examination and radiographic examination of the chest were unhelpful This history is of course suggestive of uncomplicated emphysema, but what clinched the diagnosis was observation of the patient during mild exercise When he walked briskly round the room nothing abnormal was at first noticed, but after a few minutes he was becoming uncomfortable and on halting was seen to be making respiratory efforts ...proportionate to the exercise and indeed his ventilation was probably greater than expected Moreover examination of his lips and tongue revealed a bluish tint which slowly disappeared as he recovered from the exercise

The second patient had a background disability similar to that of the first but he came under care in a ...y different way He was admitted as an emergency ...case and obviously very ill He was deeply cyanosed and his breathing was very distressed Numerous ...pitations could be heard over both lungs and the sputum was purulent The jugular pressure was raised but there was no oedema The patient responded rapidly to treatment with oxygen and antibiotics and returned to work as a hospital porter apparently none the worse

The third patient was a woman in her fifties who complained of swelling of her legs She had little cough and no sputum She was found to have considerable oedema, an enlarged liver and a raised jugular pressure—in fact she had heart failure She was strikingly cyanosed but not distressed and indeed she denied any difficulty in breathing The cyanosis could be mitigated by a voluntary increase in ventilation and was abolished by breathing oxygen which however made her stuporose

* * *

These three patients were all suffering from respiratory insufficiency the first in chronic form the second from an acute exacerbation with temporary cardiac overload of a chronic state and the third from a chronic form presenting as established cardiac failure These examples ...t so much as to make clear I hope the need for some ...y elaborate scheme of classification and to specify the patient's functional state we need I shall suggest at least four components or dimensions of classification The choice is suggested by the results of physiological measurements, but I shall first develop the ideas on a clinical basis.

The three patients described were all cyanosed though the first was so only on exercise This cyanosis was due to deficient oxygen saturation of the arterial blood and is characteristic of the disorder Indeed, we may take a decrease in arterial oxygen saturation on moderate exertion as the criterion of respiratory insufficiency

Why does the arterial saturation of such patients fall on exercise? In health this fall does not take place because ventilation increases more or less proportionately to the increase in oxygen consumption. The result is that about the same proportion of oxygen is removed from the inspired air and so there is little alteration in the composition of the alveolar air or in the gas tensions of the arterial blood If a normal subject voluntarily restrains his ventilation during exercise (and this can be managed), his arterial saturation will drop The patients we are considering behave as though their ventilation was not increasing during exercise by the normal amount But when we actually measure their ventilation we find as a rule that it is normal or somewhat raised It is clear then that they suffer from some failure to make proper use of the ventilation they achieve We may call this a *decrease in the ventilatory utilisation* which is our first functional component

We may then ask why the patients respiratory efforts are disproportionate to the exercise To some extent this may be due to excess ventilation but usually this is not itself sufficient and we conclude that the relation between mechanical effort and respiratory movement is changed so that the work cost of ventilation is increased We call this a decrease in mechanical efficiency which is our second component

Usually the patient's sense of subjective effort which probably reflects the output of the respiratory centre is in proportion to the mechanical respiratory work he is performing But sometimes this is not so For example in poliomyelitis with respiratory involvement the patient may feel very dyspnoeic—that is he is conscious of great respiratory effort, whereas the work achieved is small. We must therefore be prepared to take into account a reduction in the mechanical result of respiratory central activity a decrease in neuromuscular efficiency our third component

Finally we observe that some patients become very dyspnoeic on exercise when only slightly cyanosed while others are undistressed although grossly cyanosed at rest. Of course we should take into account also the arterial CO_2 tension and pH but when we do so we are still driven to the conclusion that there is considerable variation between patients in the response of the respiratory centre to chemical stimuli We can say that some patients have a decrease in the central sensitivity—our fourth component

Each of these components represents the relation characteristic of the patient at that time between two physiological variables which can be measured or assessed When the variables and the connecting component functions are arranged in order they form a closed loop Thus for a given metabolic rate, the ventilatory utilisation defines the relation between the *ventilation* and the blood gases determining the *chemical stimulus* The *chemical stimulus* will produce a respiratory central output or *drive* depending on the central sensitivity The *drive* will produce mechanical *work* depending on neuromuscular function and finally the mechanical function will determine what the *work* will produce in *ventilation* And so the loop is closed

The effect of this arrangement is that a deterioration in a function is not followed by a proportional change in the dependent downstream variable but by a smaller change combined with an increase in the upstream variables For example if the mechanical function and the utilisation were both halved and the total respiratory functional efficiency thus reduced to about a quarter of normal we should expect a deviation of blood gases on exercise not of four times normal but only of about twice normal, entailing about twice the normal *drive* and *work* and a near-normal *ventilation* This is a typical example of homœostasis, or, as it is now fashionable to call it, feed back stabilisation The arrangement benefits the patient by keeping the blood gases within limits as deterioration occurs, but it makes recognition of early abnormality more difficult In the above hypothetical example the *ventilation* might be normal, high, or low, according to the relative importance of the defects of mechanical function and of utilisation This emphasises the necessity of studying the relations between the physiological variables rather than the variables in isolation.

---

* Frederick W Price memorial lecture delivered at Queen's University Belfast on April 20 1955

* * *

I now turn to the methods of estimating the variables and thus inferring changes in the components These estimations may be made with differing degrees of accuracy, but the most accurate is not necessarily the most informative method, as there will nearly always be a price to be paid in applicability, continuity of measurement, and so on For many purposes of physiological research the time spent on an estimation and the coöperation required of the subject are not important limitations —in clinical research it is often quite otherwise Moreover, we can profitably use quite crude non-instrumental methods of quick clinical assessment

Thus there is no difficulty in measuring ventilation in a normal subject, but dyspnœic patients are intolerant of the usual mouth-piece and nose clip, and frequent cough and sputum may make their use impracticable Often a good compromise in such patients is continuously to record trunk expansion, which can be done without trouble to the patient, and to calibrate by a short run against a spirometer Clinically, it is fairly easy by observing trunk expansion to recognise over-ventilation during a standard exercise, if normal subjects have been observed under the same conditions One must recognise and make allowances for the see saw movements of chest and abdomen that often occur on exertion in patients with mechanical difficulties

The respiratory work is rather easily estimated by measuring intra-œsophageal pressure by means of a fine œsophageal tube, the pressure swing during the respiratory cycle multiplied by the rate of breathing is a fair index of energy used in expanding the lungs Clinically, increased force may be inferred from use of accessory muscles, indrawing of intercostal spaces, see saw movement, and so on

The respiratory drive cannot be directly measured, but it is probable that the subjective respiratory effort closely reflects it One can estimate what proportion of the maximum drive obtains at a given time by comparing the actual work or ventilation with the maximum the patient can achieve

The arterial blood pH and gas tensions which determine the chemical stimulus may be accurately measured in a sample obtained by arterial puncture but the methods are time consuming, and it may not be easy to obtain the samples—for example, during exercise A very useful instrument for clinical research is the photo electric ear oximeter, which allows the arterial oxygen saturation to be followed continuously at no inconvenience to the patient The advantage of a continuous record during exercise, hyperventilation, and oxygen breathing far outweighs any difficulties of exact calibration For clinical routine we have to rely on the recognition of central cyanosis This is notoriously difficult, but with practice and attention to detail one can often observe the fall of saturation on exercise The inside of the lower lip is probably the best place to look, and in a doubtful case it is always worth observing the effect of oxygen breathing, which often makes it clear by contrast that a patient that one might have been prepared to accept as normal was in fact too blue

By using these simple clinical methods it is ofte possible to place patients within the dimensions classification I have outlined Thus the first patien described became blue on exertion in spite of adequat ventilation He therefore had a significant defect utilisation His respiratory efforts were *unduly great fo* his ventilation, so he had a mechanical defect H subjective efforts appeared proportionate to his respiratory work on the one hand and to his cyanosis on th other There was therefore no need to invoke an alteration in neuromuscular function or in centra sensitivity By contrast, the third patient showed, striking lack of respiratory urgency in spite of dee cyanosis, and we may safely conclude that her centra sensitivity was impaired

* * *

I shall now review briefly the causes of deterioration in the different components, and must start by admitting total ignorance of the reasons why some patients retu full central sensitivity while others suffer an early and often gross decline When full sensitivity is maintained the patient complains greatly of dyspnœa, but because of his respiratory efforts maintains reasonable blood ga tensions for many years These patients are often suspected of making rather a fuss, and even of having hysterical hyperpnœa Those with more adaptabl centres have at first an easier time of it, but chronic anox heart-failure will eventually develop, and their average survival is probably shorter than that of the first group

Neuromuscular inefficiency is not commonly important factor It may occur in nervous system diseas such as poliomyelitis, or in disorders of muscle such dermatomyositis It may also be produced by abnormality of the thoracic cage rendering muscu action ineffective for example, the kypho scolio thorax may so lack stability that intercostal contract leads to a twisting of the cage with little expansion, the maximum negative pressure the patient can deve is much reduced

It is rare to find a patient with respiratory insufficien who has not at least moderate mechanical impairme Sometimes, as in severe asthma, it may be the o abnormality There are two main processes by which mechanical efficiency may be impaired The less comm is a decrease in lung distensibility due to fibrous repl ment of elastic tissue Although some degree of l fibrosis is common, serious impairment of distensibi is rare, probably because the sponge like structure al expansion even when the substance is relatively inext sible Some of the stiffest lungs I have personally inv gated have followed heavy radiotherapy One need ha add that the radiographic appearance is no guide to disability from this cause The lungs also become distensible during the pulmonary congestion of he failure The mechanism is obscure, and its discuss outside the scope of this lecture

The commoner mechanical disability is an incr resistance to the flow of air This may of course be i large airways as in tracheal compression, but usually is due to changes in the small bronchi and bronchi I would here like to interject a protest against common habit of assuming that any wheezy patie suffering from “bronchospasm” Of course it may so, but often the evidence suggests mucosal thicke or excessive exudate rather than excessive contractio bronchiolar muscle

In emphysema an airway resistance rising rapidly expiration is characteristic This is probably due to collapse of bronchioles in the absence of the normal pull from surrounding lung, and is the main cau decreased vital capacity in the common form emphysema

Limitation of vital capacity from whatever entails supernormal respiratory rates as very rases which in turn entails some wasted effort in a dead-space ventilation The importance of this ands on the airway resistance if normal, as for aple in ankylosing spondylitis, limitation of vital city causes little disability if high, as it often is mphysema, it contributes considerably to the total len.

here are two main causes for defective ventilatory ation the more apparent which is much the less mon, is a decrease in the area of alveolar membrane thickening or other impediment to diffusion A acteristic of this type of disorder is that it affects gen transport but not that of carbon dioxide This is use diffusion, being dependent on solubility, is some nty times faster for carbon dioxide and so this gas easily reach equilibrium between air and blood even n oxygen fails to do so Various diffuse chronic mmatory states—for example sarcoidosis and stosis—occasionally cause this type of defect

he commoner defect has a more subtle basis in local roportion of ventilation and perfusion One can see this can lead to inefficiency by considering a carica e of the situation in which all the blood went to one g and all the air to the other In emphysema, whether ted or associated with other disease, this type of tilation/perfusion mismatch is present in small regions oughout the lungs. It will be seen that this process airs transport of carbon dioxide as well as of oxygen ugh the latter is more affected because of its non ar dissociation curve

striking feature of the clinical course of patients h this disorder is the abrupt reversible deterioration respiratory function that accompanies a bronchiolar ction Of course some of this is due to increased way resistance, and as it is impossible to obtain mplete measurements from these very sick patients cannot say exactly how much Nevertheless, I am ly confident that infection reduces utilisation as well mechanical efficiency The practical implication is at the outlook of a patient with severe respiratory fficiency is better if his sputum is purulent for nsiderable improvement may be expected if as is usual sputum can be rendered mucoid by chemotherapy

* * *

This brings us finally to consider treatment where it st be admitted that the outlook is bleak if not entirely ren. Most can be done for increased airway resistance the sputum is purulent antibiotics are indicated; chospasm is best treated by an isoprenaline spray for persistent non-spasmodic wheezing (possibly due mucosal thickening) corticotrophin or cortisone should tried. Incidentally the method of direct estimation of way resistance indicated earlier has shown how difficult may be to assess the action of antispasmodics. In ticular, drugs with a striking general action such as ophylline given intravenously are often credited with ducing some benefit even though measurement shows change. On the other hand, I doubt whether chospasm in the strict sense, is ever completely enaline insensitive

s of central sensitivity poses an interesting thera tic problem Since the depression probably shortens patient's life one would like to attack it even though patient might not be very appreciative If an reased rate of ventilation can be maintained for several s it is reasonable to expect the centre to regain itivity as the carbon dioxide tension falls, in a way parable to the enhanced sensitivity attained at high itudes This has in fact been achieved by strenuous erventilation in a tank respirator; but this is a tour force a tank respirator being scarcely tolerable to a ient with much sputum and usually ineffective where re is much mechanical disability Another approach by the use of stimulant drugs My colleagues and I have made some trials with a nikethamide drip This is certainly effective in increasing ventilation and in arousing a patient with severe carbon-dioxide retention The difficulty is that when the patient is fully conscious he will not tolerate the drug in the high dosage required (250–500 mg per min) A personal trial at this dose level produced a most unpleasant burning and itching of the skin Another drug we have tried is salicylic acid which also increases the central response to carbon dioxide It may well be effective in some cases, but the respiratory action is difficult to dissociate from undesirable effects such as fluid retention

If one cannot be confident of restoring the sensitivity one can at least refrain from depressing it further with morphine which is indeed often rapidly fatal in these patients

In the episodes of acute insufficiency as in the second patient described earlier oxygen should be used It may be given by a tent or by a mask of the plastic nose bag type but the B L.B mask is unsatisfactory It is true that the removal of the anoxic drive decreases ventilation and so worsens the respiratory acidosis, and that this leads to drowsiness and even coma but if one is aware of it and uses common sense there is very little risk.

For chronic anoxic heart-failure therapeutic myxœdema produced by methylthiouracil has a place The patient is rendered more comfortable and may survive for several years The appearance of these deeply cyanosed myxœdematous patients is formidable and often someone is eventually moved by æsthetic considerations to interrupt treatment, with the usual sequel of a rapid return of severe failure

* * *

I hope I have made good my claim that physiological studies can help in the clinical management of respiratory insufficiency Sometimes the help is a direct estimation of some function More commonly it is by suggesting what to look for and reminding us of our errors that clinical technique is improved In this way the worker with special techniques learns new physical signs and becomes more adept at evaluating old This is an aspect of clinical research which is often undervalued

THE EFFECT OF HYDERGINE ON UTERINE ACTION

T N A JEFFCOATE
M D Lpool, F.R C.S.E F.R C O G
PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY

J K WILSON
M.B Lpool, M.R C O G
TUTOR IN OBSTETRICS

UNIVERSITY OF LIVERPOOL

IT is claimed that hydrogenation of the alkaloids of ergot deprives them of their oxytocic and vasoconstrictor properties and endows them with spasmolytic ones (Stoll 1953) with the result that they bring about decreased vascular tone, active vasodilatation relaxation of the uterus and inhibition of the action of the common oxytocics including that of ergot itself It is also reported that the hydrogenated alkaloids have a latent capacity for neutralising the effect of adrenaline and noradrenaline These claims among others are made more specifically for the combination of alkaloids marketed under the trade name of 'Hydergine'* (Stoll 1953) They are to some extent substantiated as regards various animals but, except for the relief of hypertension, have not received confirmation in man

---

* Hydergine contains the dihydro derivatives of ergocornine ergocryptine and ergocristine in equal proportion Supplies for this trial were provided by Sandoz Products Ltd

An earlier and somewhat similar preparation, dihydro ergotamine, was first reported by Gill and Farrar (1951) to have a favourable effect on human uterine action, promoting relaxation of the cervix and lower segment and quickening labour without danger to mother or fœtus This was confirmed by Gill (1953), Baskin and Crealock (1951), Hallum (1952), and Richardson (1952) Jeffcoate (1952) and Mori (1952), however, drew attention to the fact that dihydro ergotamine could produce uterine colic similar to that produced by the untreated ergot alkaloids, and warned of its danger to the fœtus This unfavourable effect was also reported by Altman et al (1952) and by Gill (1953)

The original users of dihydro-ergotamine did not control their observations, and they used it intramuscularly in divided doses In our trial (Jeffcoate et al 1953) better standardisation and control of dosage were obtained by administering dihydro ergotamine in dilute solution by intravenous drip, and records of uterine action were obtained by means of the Lorand tocograph In both normal and incoördinate labour no effect was observed on uterine action or on the course of labour when the dose was small Indeed, the only effect ever recorded (and that when the dose was increased) was an oxytocic one with a tendency to produce uterine colic much the same as that produced by the untreated ergot alkaloids

Hydergine was first used in the obstetric field by Wilhelm (1951), who reported that it had a beneficial effect in "secondary uterine inertia" He also claimed (though without giving comparable figures for untreated patients) that it considerably shortened the first stage of labour when administered routinely to primigravidæ Law (1954), however, reported the results of a controlled investigation in which he did not find any shortening of the first stage of labour from routine use of hydergine in primigravidæ

Our trials of hydergine on women in labour were made in 1953 and 1954

Materials

NORMAL LABOUR

Intravenous Hydergine

In a preliminary trial 5 primigravidæ, all in apparently normal labour, were treated with hydergine by intravenous drip Hydergine 0 6 mg was added to 1 litre of 5% dextrose, and the drip was started very slowly Thereafter the rate of flow was cautiously increased so long as no untoward effect was observed The clinical effect was assessed by observation of the frequency and character of the uterine contractions and of the site and intensity of the referred pain

Clinical observations were supplemented by the use of a Lorand tocograph This machine has obvious limitations but does permit comparative studies of gross changes in uterine action In assessing the tocographic records from these and other patients in the investigation hydergine was considered responsible for a change in the pattern of uterine activity only when the change followed within 15 minutes of starting the hydergine or changing the rate of its administration

Intramuscular Hydergine

The 109 patients in this part of the inquiry were primigravidæ in normal labour at term, and were unselected apart from the exclusion of cases of disproportion, 59 were treated, and 50 acted as controls Their labours were managed according to the routine practice of the hospital, hence they all received intramuscular morphine gr ¼ and pethidine 0 1 g when the cervix reached 2–3 fingers' dilatation The "treated" patients, however, were also given intramuscular hydergine, the first injection being given at the same time as f the morphine and pethidine The whole course d of four injections of 0 15 mg each at hourly intervals, but the course was not completed if full cervical dilatation intervened

The treated patients had been in labour for an average of 10 hr 6 min at the start of hydergine therapy, the corresponding time for the controls at the time observation was started was 10 hr 20 min The similarity of these figures testifies that the two groups were comparable.

INEFFICIENT UTERINE ACTION

In this group there were 17 patients (15 primigravidæ and 2 multiparæ) in whom, because of faulty uterine action, the first stage of labour was not progressing smoothly, and the standard treatment with morphine and pethidine had not had any noticeably good effect. 8 of the women had already been in labour for more than 24 hours when hydergine therapy was started Abnormal uterine action was diagnosed in the other 9 on the bas of clinical or tocographic evidence, or both, even though labour had been in progress for less than 24 hours

Uterine inefficiency was classified according t Jeffcoate et al (1953) as follows

	No of ca
Asymmetrical uterine action	1
Colicky uterus	3
Hypertonic lower segment	10
Hypotonic inertia	2
Cervical dystocia	1

All these patients were given intravenous hyderg by drip infusion In 12 of the cases uterine action bef and after treatment was studied with the Lor tocograph

These cases were not controlled by a similar gr in which no treatment was given, because severe undisputed uterine inefficiency does not occur of enough to allow this to be done within a reasonable ti Moreover, individual cases of faulty uterine action are different from each other, and the diagnosis depends much on personal opinion, that it is doubtful whet any two series can ever be truly comparable

HYDERGINE AND OXYTOCIN †

This small group is included because of the cla previously referred to, that hydergine can either neutra or inhibit oxytocics It consists of 4 primigravidæ gi hydergine intravenously while receiving oxytocin intravenous drip 3 for the induction of labour, and for hypotonic inertia in labour

Results

NORMAL LABOUR

Intravenous Hydergine

All the 5 patients in this group were ultima delivered vaginally 4 spontaneously, and 1 with forc The placenta was delivered normally and quickly in case, but in 3 the uterus remained hypotonic for time afterwards and its response to intravenous e metrine was sluggish 2 of these patients incurre blood-loss of 16 fl oz in the third stage and postpa period, and the other 12 fl oz

In 3 patients the site and intensity of the labour p remained unchanged after the introduction of hydr therapy, but in the 2 others the treatment seeme cause a considerable increase in the amount of experienced In these latter 2 and in 1 other cas tocographic records suggested that hydergine had oxytocic effect (fig 1) In only 1 patient did tocogr suggest a reduction in uterine activity, and this foll the infusion of 0 15 mg in only 7 minutes

Intramuscular Hydergine

Length of first stage —Patients in both the treated control series had been a similar time in labour observation or treatment was started From then

---

† The preparation used in this series was 'Pitocin' (Park & Co) in a strength of 5 units per litre of 5% dextro

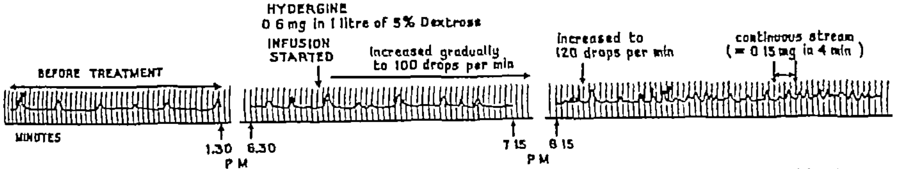

Fig 1—Record of uterine activity during successive changes in rate of hydergine drip infusion (primigravida in normal labour)

the end of the first stage of labour the average time was 5 hr 45 min in the treated and 5 hr 20 min in the untreated The average duration of the whole first stage in the two groups was thus 15 hr 51 min and 15 hr 40 min. The difference is insignificant Tables I and II show that the similarity of the two groups persists even when the figures are subdivided to show the relative lengths of the early and late parts of the first stage In general, the total duration of the first stage was proportional to the length of time taken to reach 2–3 fingers dilatation and this was true irrespective of treatment In other words when the cervix was dilating slowly it continued to do so despite treatment and the only possible effect of hydergine noted was to quicken the first stage slightly in those cases where it was already proceeding rapidly

Length of second stage—The second stage lasted an average of 50 min. in the treated patients and 48 min the controls.

Method of termination of labour—In 2 of the hydergine treated patients forceps delivery was undertaken hile there was still a narrow rim of cervix present his was because in 1 case the cord prolapsed and in the ther case hæmorrhage and signs of fœtal asphyxia sulted from premature separation of the placenta further patients in the treated group were delivered ith forceps for the following reasons

	No of cases
Failure of voluntary effort	2
Deep transverse arrest	4
Prophylactic	5
Intrapartum hæmorrhage	1
Fœtal distress	5

f the 7 cases of forceps delivery in the controls 4 were prophylactic and 3 were for fœtal distress Forceps livery took place more often in the treated group %) but it is doubtful how much importance to tach to the difference in interference rates because the beral use of forceps by some members of the staff could fully explain coincidental differences of a high magnitude

BLE I—PRIMIGRAVIDÆ IN NORMAL LABOUR WHO RECEIVED INTRAMUSCULAR HYDERGINE

ours in labour before mmencing treatment in reaching 2–3 fingers dilatation)	Time taken to complete dilatation (hours after start of treatment)					
	0–4	4–8	8–12	12–16	16–20	More than 20
8 (18 patients)	16	3	1			
16 (18 patients)	13	0	4	1		1
re than 16 (11 patients)	4	2	3		1	2

BLE II—PRIMIGRAVIDÆ IN NORMAL LABOUR (UNTREATED)

urs in labour before rt of observation (i e reaching 2 3 fingers' dilatation)	Time taken to complete dilatation (hours after start of observation)					
	0–4	4–8	8–12	12–16	16–20	Over 20
8 (22 patients)	13	7	1			1
16 (19 patients)	9	6	4			
re than 16 (9 patients)	3	3	1	1	1	

In the hospital in question the forceps rate among all primigravidæ is 18%

Third stage and immediate postpartum period—Manual removal of the placenta was not necessary in any patient, treated or untreated The placenta was always delivered within 25 min and usually within 10 min of delivery of the baby According to the routine practice of the hospital all the controls and 40 of the treated had an intramuscular injection of ergometrine 0 5 mg on completion of the third stage The 10 other hydergine treated patients had 10 units of intramuscular oxytocin The average blood loss incurred by the controls during and after the third stage was 7 fl. oz In the treated patients who were given ergometrine the loss averaged $7^3/_4$ fl. oz and in those who had pitocin 12 fl oz 8 treated patients lost more than 20 fl oz and 2 required transfusions of blood or plasma substitute Of the controls 3 bled more than 20 fl oz and 1 required transfusion Again the differences are insignificant

Fœtus—Fœtal asphyxia before delivery was evident in 7 of the treated cases and in 3 of the controls In 2 of the treated, however it was explained by retroplacental hæmorrhage Neonatal asphyxia sufficient to excite comment developed in the babies of 17 treated mothers and 24 controls The number of cases causing anxiety on the part of the attendants was 3 in the treated group and 4 in the controls Among the treated cases there were 3 stillbirths, but 2 of these were explained by accidental antepartum hæmorrhage which though not clinically evident during labour gave proof of its occurrence by the presence of old clot on the maternal surface of the placenta

INEFFICIENT UTERINE ACTION

Length of First Stage

In 15 of the 17 patients in this group the cervix was less than 3 fingers dilated at the start of the hydergine therapy In the 2 other cases the dilatation was stationary at the 4 fingers stage The cervix became fully dilated in all cases but in 1 which was classified as cervical dystocia no change took place until the resistance of the external os was overcome by digital stretching whereupon dilatation proceeded quickly The longest interval from the start of hydergine therapy to full cervical dilatation was $7^1/_2$ hours

Method of Delivery

2 patients were delivered by cæsarean section 1 was a primigravida aged 35 with a small pelvic outlet in whom a trial of forceps was abandoned The other was a primigravida whose pelvic cavity was smaller than was originally thought and the presenting head did not descend low enough for safe forceps delivery

10 patients had spontaneous deliveries and 4 were assisted with forceps The remaining case was one of twins the first fœtus having assisted breech delivery and the second being extracted with forceps

Sensation of Pain

There were 9 patients in whom low back pain was excessive and after the administration of hydergine this pain was increased in severity in 5 unchanged in 3 and relieved in 1 Another patient who complained of severe

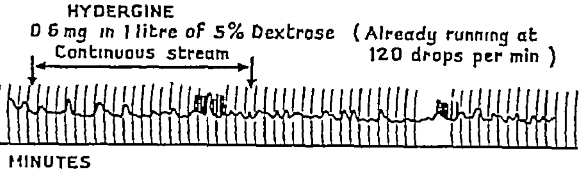

Fig 2—Record of uterine activity during rapid infusion of hydergine (primigravida with inefficient uterine action)

hypogastric colic, suffered a sharp exacerbation when hydergine treatment was begun The 6 women whose pain was increased had to be given pethidine intravenously

Tocographic Evidence

Tocographs were obtained before and after treatment in 12 cases In 5 the base line, the frequency and amplitude of the contractions, and the general pattern of the tracings underwent a change which indicated an increase in uterine activity (figs 2 and 3) In 2 patients a reduction in uterine activity was recorded, and in the remaining 5 there was no change

Third Stage and Postpartum Period

Uterine atony during the third stage and immediate postpartum phase was observed in 2 patients who lost 26 fl oz and 27 fl oz of blood In all the others uterine action was satisfactory during this period, and the placenta and membranes were delivered without event

Fœtus

Signs of fœtal asphyxia were observed at the end of the first stage of labour in 1 case, but this infant was subsequently found to have a minor degree of exomphalos In 1 other case a mild degree of neonatal asphyxia developed but required no special treatment There were no stillbirths or neonatal deaths

OXYTOCIN-INDUCED UTERINE CONTRACTIONS

The 4 women in this group were all receiving an oxytocin drip infusion for the purpose of inducing labour or treating hypotonic inertia Hydergine was added to the drip when uterine contractions were strong and regular In 2 cases hydergine appeared to increase the frequency and strength of the contractions (fig 4) and the intensity of the patient's pain A modified oxytocic effect was also suggested in the tocograph of the third patient the effect of oxytocin was accentuated while the hydergine was introduced at the rate of 90 drops a minute, but, when the infusion was increased to a continuous stream, the contractions were reduced in amplitude but not in frequency In the remaining case the oxytocin induced contractions were less intense after the introduction of the hydergine

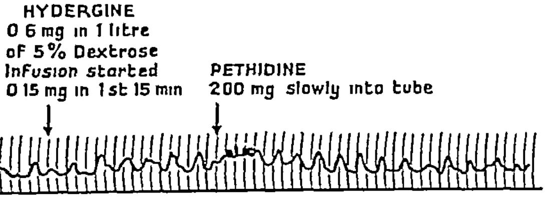

Fig 3—Record of uterine activity during rapid infusion of hydergine (primigravida with inefficient uterine action)

Incidentally, the 3 women who were receiving oxytocin with the object of inducing labour did not enter labour, contractions dying away as soon as the drip was discontinued A combination of oxytocin and hydergine given by repeated intramuscular injections was tried as a of inducing labour in 6 further women and it ısuccessful in all

Discussion

The almost identical progress of treated and untreated women in normal labour confirms the findings reported by Law (1954) and indicates that no advantage is to be gained from the routine administration of hydergine, which does not materially influence the speed and smoothness of the first stage Moreover there is nothing to support the idea that hydergine favours relaxation of the cervix and lower segment

As regards inefficient uterine action the findings were inconclusive, if only because the assay could not be controlled The fact that all the patients reached full cervical dilation in less than 7½ hours after the start of treatment at first suggests that hydergine may have had some effect on the labours However, such an interpretation is open to question, since many of the patients had large amounts of pethidine—usually intravenously—for the relief of their intense pains, and it is known that pethidine sometimes exerts a corrective effect on the disorderly uterus

If it is concluded that hydergine did quicken some, if not all, of the labours, the evidence suggests that it usually did so by exerting an oxytocic action rather th by reducing hypertonus There were only 2 women whom it may have had a quietening and regulating effe on uterine behaviour

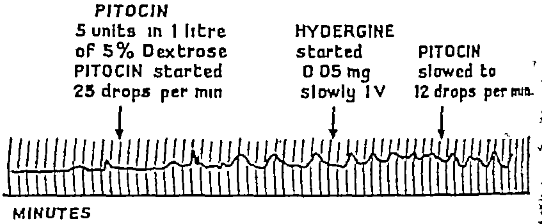

Fig 4—Record of uterine activity under influence of oxytocin alone of oxytocin and hydergine simultaneously (primigravida under oxytocin induction of labour)

The failure of hydergine to inhibit contractions induce with oxytocin, and the finding that in some cases it act synergistically rather than antagonistically, are keeping with this conclusion

A possible inhibitory action of hydergine is suggeste by the tendency to uterine relaxation and hæmorrha during and after the third stage in women who h received intravenous hydergine This observation, ho ever, may be better explained by the withdrawal of oxytocic action when the drip was discontinued at time of full cervical dilatation Moreover a simil phenomenon is reported when ergometrine or other er alkaloids are used intravenously during labour ra than being reserved until delivery is complete (Bick 1943, McConnell and Schauffler 1943)

If the only demonstrable effect of hydergine is an ox tocic one, it may well be that, like dihydro ergotami it can induce hypertonus when given in large do The tocographic records suggested such an effect some patients, but in none did it develop to a se degree or threaten the life of the fœtus It ther seems that its oxytocic action is not so strong or danger as that of dihydro ergotamine, and the same is true of alkaloids from which each is derived

Conclusion

Despite laboratory evidence to the contrary, the re of this clinical investigation indicate that the hydr genation of the ergot alkaloids does not deprive th of their oxytocic action, let alone reverse it The pe tence of this property means that their use involves which is not compensated by any other demon effect on uterine efficiency.

Of all mammals only man, apes, and the dalmatian coach hound excrete substantial amounts of uric acid in the urine In man the renal mechanism of excreting uric acid consists in complete filtration of plasma urate by the glomeruli and active reabsorption of about 90% by the proximal tubules (Berliner et al 1950) the net clearance of urate is thus reduced to but a tenth of the glomerular filtration rate Drugs which increase the excretion of urate—e.g , salicylate, cinchophen probenecid ('Benemid'), phenylbutazone, and cortisone—do so by impairing its active reabsorption by the tubules and thereby increasing its renal clearance (Beyer et al 1951 Berliner 1954) These and similar substances are called uricosuric agents, of which some occupy an important place in the modern management of gout

The biochemical processes in the tubule cell with which they interfere are far from elucidated but a relationship exists (Talbott 1943 Beyer et al. 1951) between the reabsorption of urate and the active tubular secretion of certain other organic molecules—e.g phenol sulphonphthalein (P.S.P) *p* aminohippurate (P A.H), *p*-aminosalicylate (P A.S), diodone, and penicillin (fig 1) The cellular transport mechanism for reabsorbing urate thus shares one or more steps with the tubular secretion of these foreign compounds Loading the tubules with one of these substances will competitively depress the passage of any of the other members of the group For example P.A H. depresses the secretion of penicillin and P.S P the reabsorption of urate Similarly agents which are not secreted but appear to block some phase in the enzymatic transport process—e g carinamide and probenecid—will impair the tubular passage of any of the foregoing compounds. Probenecid was first used like its less well tolerated precursor carinamide for maintaining the blood levels of penicillin and P A.S by inhibiting their renal tubular secretion The further ability of carinamide and probenecid to impair the reabsorption of urate was first applied by Wolfson et al (1948) and Gutman (1951) to the uricosuric treatment of gout.

Probenecid (Gutman and Yü 1951 Horwitz and Sougin Mibashan 1953, 1955) and salicylate (Marson 1953) are currently the most effective uricosuric drugs for prolonged use Of the two probenecid has the advantages of great potency in small dosage (0 5–1 5 g daily) and negligible toxicity and its biochemical and clinical effectiveness are relatively preserved even in the presence of renal disease (Sougin Mibashan 1954)

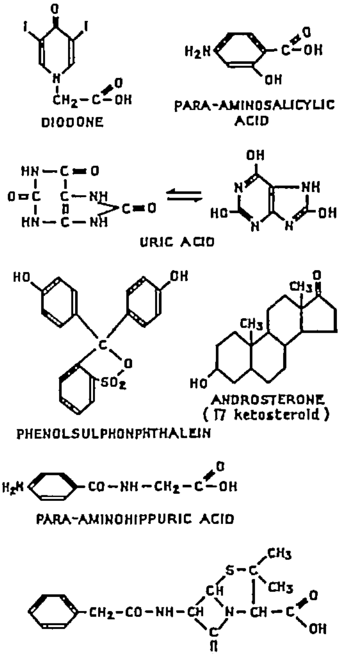

Fig 1—Compounds sharing the same system of renal tubular transport.

Discovery

Ethyl biscoumacetate ('Tromexan') is a synthetic anticoagulant introduced a few years ago for the clinical management of thrombo-embolic disease Compared with the closely related dicoumarol, it has the advantages of speedier increase in the prothrombin time and quicker return to normal when it is withheld A typical effective single oral dose in man is 1 5 g making it about a fifth as potent as dicoumarol (Wright 1952) The uricosuric properties of ethyl biscoumacetate were first observed in the following circumstances

Gout is common in Cape Town, hundreds of cases having been observed among its half million people in the past few years. Clinical and metabolic studies of the continuous use of probenecid in fifty cases of gout for 6–30 months have been reported by Horwitz and Sougin Mibashan (1953 1955) During these studies a certain patient (case 82 of our series) was admitted to hospital for clinical assessment In addition to the recent onset of episodic arthritis, which responded to colchicine and with which there was hyperuricæmia he also had symptomless auricular fibrillation. There was no other clinical or cardiographic evidence of heart disease and it was decided to treat him with quinidine to correct the arrhythmia. As the arrhythmia was presumably of long duration anticoagulant measures were taken as well guided by daily prothrombin estimations.

After a day or two of treatment with quinidine and ethyl biscoumacetate it was observed from serial urate determinations that the patient was no longer hyperuricæmic (fig 2) When the drugs were discontinued because of failure to restore normal rhythm the serum urate rose to its former high level Simultaneously less urate was excreted, and the urinary urate/creatinine ratio decreased

This coincidence of events prompted treatment with ethyl biscoumacetate alone The metabolic results (fig 2) were indistinguishable from those which might have been produced by a potent uricosuric agent such as probenecid. Fig 3 illustrates the effect of ethyl bis

coumacetate given for 10 days to another gout patient (case 8), followed several weeks later by probenecid therapy This patient had chronic renal disease with a serum-urea level of nearly 100 mg per 100 ml The uricosuric response of a falling serum urate level and rising urinary excretion of urate occurred with both drugs There was no clear relationship, during treatment with ethyl biscoumacetate, between either the serum-urate level or the urinary output of urate and the daily prothrombin value

Confirmatory Experiments

MAN

Effect of Single Oral Dose of Ethyl Biscoumacetate on Serum urate Level

Four gout patients, three patients with coronary disease without overt cardiac or renal failure, one orthopædic patient in good general health, and one normal subject were each given either 1 2 or 1 5 g of ethyl biscoumacetate in one oral dose The serum-urate level was measured, by the method of Herman Brown (1945), before the drug was given and one or more times in the succeeding 24 hours The results are illustrated in fig 4, the lowest serum-urate level after the administration of ethyl biscoumacetate being used Prothrombin-times were measured by Quick's one stage method before and after the administration of ethyl biscoumacetate

In every instance there was an impressive fall in the serum urate level, ranging from 40% in the normal subject to 12% in one of the gout patients (a woman with severe hypertension and slight renal impairment) Case 8, with tophaceous gout and severe renal disease, showed a 22% fall The earliest clear cut reduction was found 1–2 hours after the administration of ethyl biscoumacetate, and the greatest fall after 5 hours in two subjects observed at short intervals, in these people the prothrombin time did not lengthen until next day

Effect of Ethyl Biscoumacetate on Renal Clearance of Urate and on Urate/Creatinine Clearance Ratio

Methods—Clearance experiments were done under standard conditions, in the morning, at rest, and after liberal hydration and a snack breakfast Spontaneously voided urine was collected at carefully timed intervals of about 30 minutes When clearance collections were continued for many hours, as in R S M and case 12, the periods were sometimes longer Patients were instructed in the technique of emptying the bladder, and the first collection was usually regarded as a practice one Subjects apparently lacking satisfactory control of their bladders were excluded To obviate changes in clearance of urate at small flows of urine (Brochner Mortensen 1940), collections of less than 2 ml per min (rare with good hydration) were not used In both serum and urine the amount of urate was determined by Brown's (1945) method and of creatinine by the method of Bonsnes and Taussky (1945) No intravenous priming being used, the clearance values represented the endogenous chromogens Venous blood was drawn usually every clearance period, but in longer experiments a serum determination sometimes served its own and the succeeding period The clearance of endogenous creatinine is in accepted use as an expression of glomerular filtration rate (G F R.) in man and dog (Homer Smith 1951) Standard values in man for a body surface area of 1 73 sq m are about 10 ml per minute for urate clearance, and 127 and 117 ml per minute for G F.R. in men and women respectively (Gutman and Yü 1951, Homer Smith 1951)

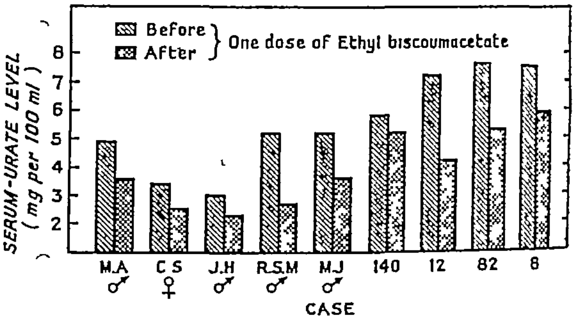

Fig 4—Effect of single oral dose of ethyl biscoumacetate on serum-urate level in 5 non-gouty and 4 gouty persons.

Results—The effect of ethyl biscoumacetate on the urate/creatinine clearance ratios of four gout patients and one normal is shown in fig 5 In case 82 the clearance tests were done a week apart,

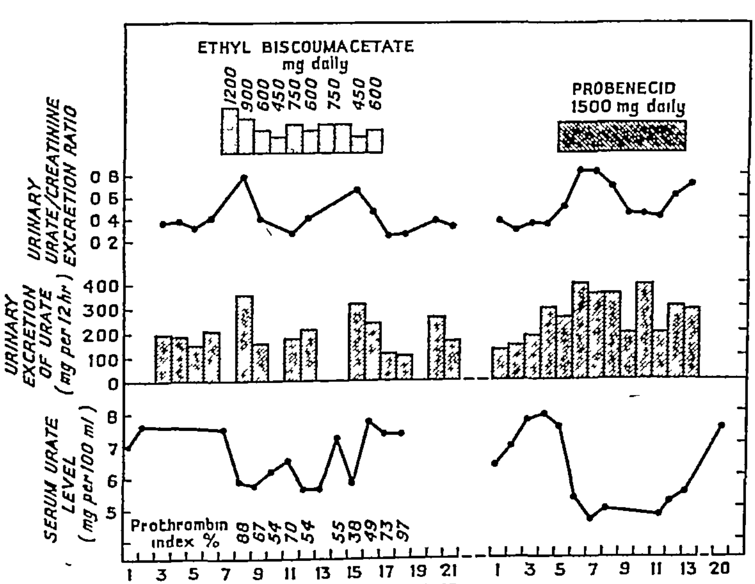

Fig [illegible] of ethyl biscoumacetate, and subsequently probenecid, in case 8 (gout with chronic renal disease)

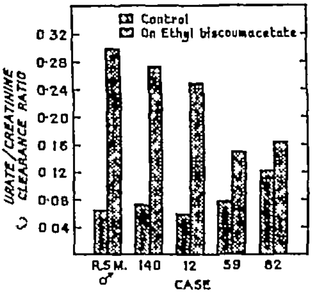

Fig 5—Effect of single oral dose of ethyl biscoumacetate on urate/creatinine clearance ratio in 1 normal subject and 4 patients with gout.

the second during a course of treatment with ethyl biscoumacetate. All the others had clearances done for several successive periods immediately before and after one oral dose of ethyl biscoumacetate The smallest dose was 1 2 g (case 140) and the largest 1 8 g (R. S M.) The histograms in fig 5 represent the average clearance values of 2–4 collection periods before the ingestion of ethyl biscoumacetate and 3–10 collection periods following the drug The rise in urate clearance and hence in the urate/creatinine clearance ratio is impressive the latter increasing by as much as 370% in one case The G.F.R underwent no significant change

The accompanying table shows the detailed results obtained in R S M. and case 12 each of whom had a diurnal series of clearance determinations with the following noteworthy observations

(1) The first steep rise in urate clearance took place less than 2 hours after the administration of ethyl biscoumacetate denoting a lag of 1–2 hours after ingestion before a uricosuric effect was produced. This is the time known to be taken for the absorption of ethyl biscoumacetate (Brodie et al 1952)

(2) The greatest increase in urate/creatinine clearance ratio attained in any single period was 480% (0·064–0 309) and 660% (0 038–0 ·60)

(3) A significant increase in urate clearance preceded the first distinct fall in serum urate level in keeping with a renal site of uricosuric action.

EFFECT OF ETHYL BISCOUMACETATE ON RENAL CLEARANCE OF URATE AND ON URATE/CREATININE CLEARANCE RATIO IN ONE NORMAL AND ONE GOUT SUBJECT

Subject	Time (min)	Urine flow (ml. per min)	Creatinine		Urate		Urate/creatinine clearance ratio	Prothrombin index (%)

(4) Early slight loss of serum urate unassociated with increased clearance was detectable apparently as a result of copious diuresis.

(5) Prothrombin activity stayed at 100% when the urate clearance had already greatly increased In this and other experiments the impairment of prothrombin after one dose of ethyl biscoumacetate was first detected after the serum urate had already begun to return to normal, usually on the day following the administration of ethyl biscoumacetate. This conforms to the recognised lag in the anticoagulant effect of ethyl biscoumacetate in clinical use

RAT

The main end product of purine metabolism in mammals other than primates and the dalmatian dog is allantoin which is derived from its precursor uric acid by the action of uricase, an enzyme present mainly in the liver Uric acid in the blood and urine of most mammals exists therefore by virtue of not yet having undergone complete uricolysis and its concentration in both is accordingly low Its renal excretion though small appears to follow a pattern of filtration and partial reabsorption essentially similar to that observed in man (*Byers et al* 1947)

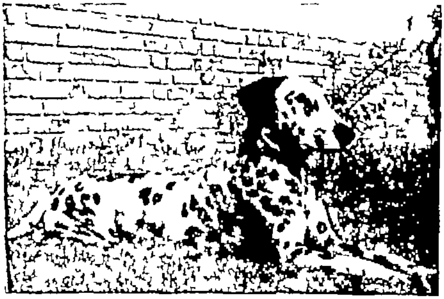

Fig 4—Dalmatian coach-hound.

Ethyl biscoumacetate given by mouth to fourteen rats and probenecid given by mouth to fourteen other rats produced similar uricosuric effects. Serum urate and urine urate levels were measured in hourly samples collected for 2 hours before and 5 hours after the giving of each drug In each case the level in the urine rose and that in the serum fell offering further evidence of the similarity of the actions of ethyl biscoumacetate and probenecid

DALMATIAN COACH HOUND AND MONGREL DOG

The singular spotted appearance of the dalmatian breed (fig 6) is genetically correlated with a unique pattern of urate metabolism (Friedman and Byers 1948 Wolfson et al. 1950)

(1) The urine contains large amounts of urate and relatively little allantoin

(2) The urinary excretion of urate is disproportionately large compared with that in man and is accomplished at a much lower plasma urate level—i.e the renal clearance of urate is very high.

(3) The high clearance is due to a renal tubular anomaly whereby urate is not reabsorbed from the glomerular filtrate The body therefore loses urate that would have been converted to allantoin, the formation and excretion of which are consequently diminished The low output of allantoin may in addition partly be due to lessened activity of hepatic uricase (Friedman and Byers 1948)

(4) The demonstration (Wolfson et al. 1950 Beyer et al. 1951) that the clearance of urate in the dalmatian exceeds the G.F.R indicates not merely a failure of reabsorption but also active tubular secretion contributing to the high renal clearance of urate

(5) Uricosuric agents which act by impairing reabsorption of urate are ineffective in the dalmatian, this process being absent (Miller et al 1951, Beyer et al 1951) As might be expected if urate is actively secreted by the tubules, Beyer et al (1951) further observed that the urate/creatinine clearance ratio (greater than 1 0 in the dalmatian) was not only not increased when probenecid was given, but even was diminished, while the plasma urate level rose slightly

This inverted response by the dalmatian to uricosuric agents, resulting from its reversed renal tubular transport mechanism for urate, enables this animal to be used for pin-pointing the renal site of action of a uricosuric drug The following experiments show that ethyl biscoumacetate is uricosuric in the mongrel dog, confirm the active tubular secretion of urate in the dalmatian coach-hound, and establish the action of ethyl biscoumacetate as a transport inhibitor able to impair the passage of urate in either direction through the renal tubule cell.

Methods

The mongrel was a healthy adult female weighing 18 kg, and the dalmatian a pure bred young male weighing 16 kg Both were kept on a normal balanced diet except for deprivation of solid food for 15 hours before each experiment The dogs drank water freely before the tests, and were given half a litre by stomach tube during the 2 hours before clearance collections began To ensure adequate diuresis and to provide a route for administering drugs, 0 6% saline solution was given by venoclysis at a fairly constant rate of 2 ml a minute throughout the procedure Limb veins were entered percutaneously with a 20 gauge short-bevel Luer Lok needle attached to an infusion set Light anæsthesia was maintained with pentobarbital sodium, 20 mg per kg body-weight, given intraperitoneally, with small intravenous additions as required A series of endogenous urate and creatinine clearances was determined for each dog before and after the intravenous administration of probenecid and ethyl biscoumacetate, intervals of at least a week separating the administration of the two drugs in each dog Though analytical quantities of urate and creatinine would have been enhanced by priming with these substances, avoidance of the exogenous technique carried the advantages of simplicity, greater freedom in the duration of clearance periods and in the timing of mid point blood samples, greater freedom in the rate of flow of the intravenous infusion, and absence of possible reactions to alkaline solutions of urate

Each experiment comprised 9–14 clearance periods extending over 5 or more hours Urine was collected at carefully timed intervals through an indwelling catheter with the aid of suprapubic pressure and air displacement Blood samples for urate, creatinine, and prothrombin estimations were obtained by direct puncture of limb veins other than the one being infused, because of the low serum levels of both chromogens the mean of several values before and after administering each drug was used in calculating all the clearance figures in a particular experiment

Intravenous administration of both test agents was desirable in these series of short term clearances Solutions of ethyl biscoumacetate and probenecid (both weak acids), containing 1000 mg in 20 ml, were prepared by extraction from the crushed tablets with equivalent proportions of warm dilute NaOH, and filtering The pH of the solution was adjusted to neutrality short of precipitating the free compound, and sterilised through a Seitz filter After several control clearance collections the drugs were given by injection of half the chosen dose and infusion of the remainder at the drip rate The mongrel received 60 mg of probenecid per kg of body weight in the first experiment, and 45 mg of ethyl biscoumacetate per kg of body weight in the second In the absence of mishap with the mongrel, the dalmatian was given twice the amount of each drug to facilitate the more difficult detection of a possibly lowered urate/creatinine clearance ratio

Results

The results are summarised in fig 7 In general, excellent urine flows were maintained during the clearance procedures, and the G.F.R remained relatively constant

Mongrel —The injection of probenecid was associated with a striking uricosuric response Compared with the average con[illegible]es, the urate/creatinine clearance ratio increased by a [illegible] of 97% and a mean of 73% (fig 7) When ethyl biscoumacetate was given, urate/creatinine clearance was increased by a maximum of 63% and a mean of 26%. (Statistical analysis of these results by difference of means, using 'Student *t*' distribution, shows them to be highly significant at a 1% level)

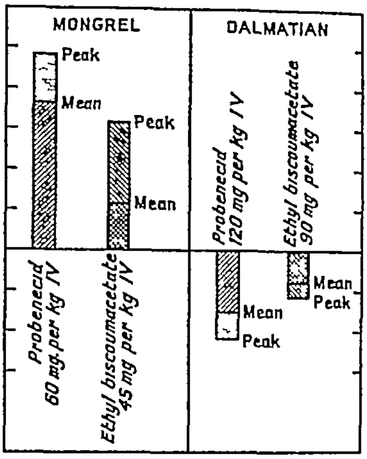

Fig 7—Effects of probenecid and of ethyl biscoumacetate on urate/creatinine clearance ratio in a mongrel and in a dalmatian dog

For both agents the increased urate clearance became apparent a few minutes after their intravenous administration, contrasting with the rather longer lag after oral dosage in man and rat Prothrombin impairment by ethyl biscoumacetate was again a later event, occurring between the 2nd and 3rd hours

Dalmation —In both experiments the normal urate/creatinine clearance ratio was substantially greater than 1 0, which supports the active tubular secretion of urate in the dalmatian. The possibility of falsely high ratios due to errors in the *absolute clearance values is offset by the further* positive action of the transport inhibitor probenecid in reducing the calculated values for urate/creatinine clearance, thus providing independent evidence of a tubular secretory mechanism.

The results confirm the action of ethyl biscoumacetate as an inhibitor of renal tubular transport of urate The urate/creatinine clearance ratio decreased from a mean control figure of 1 12 to a mean of 0 94, a 16% reduction. The greatest single reduction was 23% (After administration *of probenecid in larger dosage on a* different day the reductions were 30% and 44% respectively) Analysis of results for each experiment, using 'Student *t*' distribution, shows that, with the number of determinations involved, the results are statistically significant The smallish percentage changes should be viewed in the light of their negative direction and the total amount of urate which they represent in the dalmatian The prothrombin index was not reduced during the experiment

OTHER TUBULAR TRANSPORT FUNCTIONS

Since urate reabsorption is served by a transport mechanism which is also used for the tubular secretion of certain organic compounds (fig 1), it was desirable to know whether ethyl biscoumacetate, like other uricosuric agents, could impair the tubular transport of these substances

P A.H —The effect of ethyl biscoumacetate on the tubular transport of P.A.H was studied in a normal subject by determining the maximum tubular secretory capacity (Tm_{PAH}) before and after a single oral dose of the drug Urate and creatinine clearances were simultaneoulsy measured Fig 8 shows that Tm_{PAH} was progressively reduced, starting 1 to $1^1/_2$ hours after the dose of ethyl biscoumacetate, at the same time as urate clearance and the urate/creatinine clearance ratio increased

Penicillin —A limited investigation was made of serum penicillin levels in two men, after a standard intramuscular injection of the sodium salt given alone and during the oral administration of ethyl biscoumacetate The results suggest that ethyl biscoumacetate slightly delays the excretion penicillin, and the degree of interference if any should be further studied by penicillin-clearance techniques. Similar estimations after the administration of probenecid showed unequivocal retention of penicillin and it seems possible that ethyl biscoumacetate does not exert an effect comparable to that of probenecid on this particular tubular transport passenger

P.S.P—In another limited investigation the urinary excretion of P.S.P after a standard intravenous injection in two men, was impressively delayed up to 2 hours later when ethyl biscoumacetate was administered orally before the dye

17 Ketosteroids.—Among the properties of probenecid is the interesting ability to diminish the urinary excretion of endogenous 17 ketosteroids (Gardner et al 1951) presumably by impairment of a tubular secretory mechanism in common with the foregoing group of compounds. We have not had the opportunity to compare the effect of ethyl biscoumacetate except in one instance with negative results The problem deserves investigation, together with many others arising from the renal activities of this drug

Implications

Modification of a metabolic process by a chemical compound is always interesting When, as in the present case the observation implicates such widely separated topics as blood coagulation, the biochemistry of gout coronary atherosclerosis, hepatic and renal function, and mechanisms of rheumatic inflammation the scope for further research and correlation is unusually wide

PHARMACOLOGICAL RELATIONSHIP OF URICOSURIC, ANTICOAGULANT AND ANTIRHEUMATIC DRUGS

Ethyl biscoumacetate is not the first compound whose molecule combines uricosuric and anticoagulant properties. Salicylate and cinchophen are both potent eliminators of urate and each can impair prothrombin activity experimentally or as a clinical complication (Hueper 1946 Glazebrook and Cookson 1947) This suggests that the separate processes of urate transport by renal tubule cells and of the production of prothrombin and factor VII by hepatic cells are chemically related and may be competitively inhibited or otherwise suppressed by the same agents The delay before prothrombin time is affected after the ingestion of ethyl biscoumacetate in contrast to the early uricosuric response, seems explicable by the time required for depleting the plasma of its clotting factors Chemical interference with their enzymatic synthesis in the liver may well begin promptly after the alimentary absorption of ethyl biscoumacetate as the inhibition of renal tubular transport mechanisms appears to do

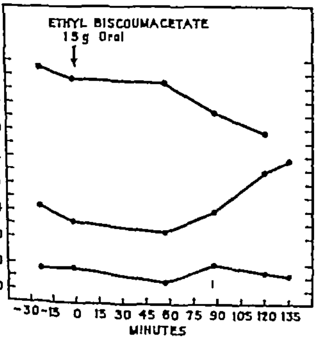

FIG 3—Renal tubular reabsorption of urate and maximal secretory capacity for P.A.H simultaneously impaired after administration of ethyl biscoumacetate. (Normal subject, primed with P.A.H at [illegible] minutes.)

The absence of manifest anticoagulant activity by uricosuric agents like probenecid and phenylbutazone and the widely varying degrees of it displayed by ethyl biscoumacetate salicylate and cinchophen, may be related to differences in their tissue distribution, solubilities excretory mechanisms, or metabolic breakdown—factors which modify pharmacological action to a high degree Moreover among the established uricosuric agents, more than one mechanism is recognised by which tubular transport may be hindered—e g cinchophen and the experimental compound dehydro acetic acid (D.H A) are inhibitors of succinic dehydrogenase (Shideman and Rene 1951) whereas probenecid is believed to block a conjugative step served by co-enzyme A (Taggart 1954) Possibly only those uricosuric agents which act at a certain point in the transport mechanism can disturb a corresponding step in the synthesis of factor VII

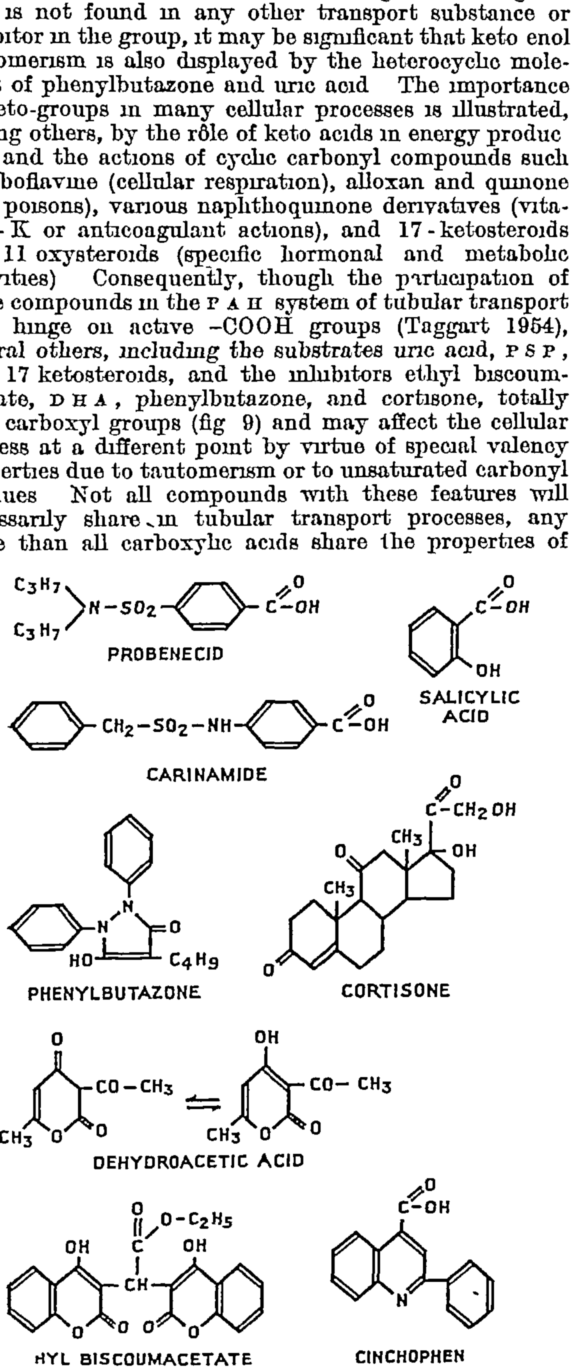
It remains to explore the truth of the latter possibility to study the effect of other coumarin compounds on renal tubular processes and to test the ability of vitamin K to protect tubular transport mechanisms against inhibition by ethyl biscoumacetate For several reasons it is conceivable that vitamin K in vivo might not necessarily oppose the renal activities of ethyl biscoumacetate in the same way as it protects the hepatic synthesis of clotting factors.

It is opportune to remark on two other significant combinations of pharmacological function One is the striking regularity with which antirheumatic or antiphlogistic drugs like salicylate, cinchophen cortisone, and phenylbutazone are simultaneously uricosuric a property discovered in each case after clinical introduction of the drug *The other concerns* several reports of the use of various anticoagulants in the treatment of acute rheumatic fever rheumatoid arthritis and gout Consistency is lacking in the premises underlying such treatment in the drugs used and in the clinical results. Howe et al (1952) were impressed by the antiphlogistic effect of heparin and its synthetic analogue Paritol in acute gout remarking that no simultaneous uricosuric effect was detected. Glazebrook and Wrigley (1949) in the light of work correlating salicylate with antihyaluronidase activity treated acute rheumatic fever with heparin (also a strong inhibitor of hyaluronidase) without special success They suggested that antihyaluronidase activity might also be a property of dicoumarol, as it is of the chemical derivative salicylate We wonder whether ethyl biscoumacetate (which functionally resembles salicylate and cinchophen in impairing prothrombin activity and, like salicylate, cinchophen cortisone and phenylbutazone, impairs the reabsorption of urate) also shares their antirheumatic and/or antihyaluronidase activity

We feel that these reflections, if somewhat ingenuous emphasise the importance of correlating biochemical knowledge in three apparently separate spheres—tubular transport of urate hepatic synthesis of clotting factors and rheumatic or gouty inflammation of connective tissue For one chemical compound to affect the function of two or more tissues (liver kidney nervous system bone marrow) is not unusual To do so not apparently by crude impairment of vital cellular activities (as occurs with many chemical poisons) but by highly selective interference with one of many cellular functions in both kidney and liver (as appears to be the case with ethyl biscoumacetate) is more remarkable

RELATION OF URICOSURIC ACTION TO CHEMICAL STRUCTURE

The difficulties of explaining the tubular transport mechanism for urate P.A.H &c in terms of molecular structure of the participants have been emphasised by Beyer (1950) Taggart (1954) and Sougin Mibashan (1954) The addition of ethyl biscoumacetate to the field does not appear to be of immediate help in identifying a particular key group determining participation in, or inhibition of, tubular transport (fig 9) The fact that compounds resembling ethyl biscoumacetate may yield salicylate on chemical degradation is of limited note, as it was in originally trying to explain their anticoagulant action (Overman et al 1944) One point of special interest, however, is the structural resemblance between part of the molecule of ethyl biscoumacetate and that of D H A , an experimentally used transport inhibitor believed to act specifically by impairing energy-production from succinate oxidation at a certain point in the mechanism (Shideman and Rene 1951) Both ethyl biscoumacetate and D.H A possess a lactone ring with a carbon residue at the 3-position and a propensity for 2, 4-keto enol tautomerism , and, though this configuration is not found in any other transport substance or inhibitor in the group, it may be significant that keto enol tautomerism is also displayed by the heterocyclic molecules of phenylbutazone and uric acid The importance of keto-groups in many cellular processes is illustrated, among others, by the rôle of keto acids in energy production and the actions of cyclic carbonyl compounds such as riboflavine (cellular respiration), alloxan and quinone (cell poisons), various naphthoquinone derivatives (vitamin - K or anticoagulant actions), and 17 - ketosteroids and 11 oxysteroids (specific hormonal and metabolic activities) Consequently, though the participation of some compounds in the P A H system of tubular transport may hinge on active –COOH groups (Taggart 1954), several others, including the substrates uric acid, P S P , and 17 ketosteroids, and the inhibitors ethyl biscoumacetate, D H A , phenylbutazone, and cortisone, totally lack carboxyl groups (fig 9) and may affect the cellular process at a different point by virtue of special valency properties due to tautomerism or to unsaturated carbonyl residues Not all compounds with these features will necessarily share in tubular transport processes, any more than all carboxylic acids share the properties of P A H or probenecid , equally important molecular factors determining solubility, distribution, breakdown, and excretion must first combine suitably to admit the compound to the renal mechanisms



suppressing the " urate-P.A.H " system of renal tubular transport.

CLINICAL APPLICATIONS

It is unlikely that ethyl biscoumacetate, whose anticoagulant properties have established it in the treatment of thrombo embolic disease, would be used in other possible rôles except in special circumstances Moreover, a potent and well-tolerated uricosuric agent like probenecid would not easily be displaced in the management of gout by any drug unless it carried distinct advantages

From our present experiments, and from many similar observations made with probenecid (Gutman and Yü 1951, Sougin-Mibashan 1954), the uricosuric potencies of ethyl biscoumacetate and probenecid appear to be roughly of the same order, 1 5 g of each producing something like a 40% fall in serum urate level and a twofold to fivefold increase or more in urate clearance If statistically valid figures supported this comparison, the greater molecular weight of ethyl biscoumacetate would give it a higher equivalent uricosuric potency than that of probenecid.

Although the use of ethyl biscoumacetate might be neat, therefore, *in treating myocardial infarction in a* gout patient, there would be practical value in finding a related coumarin compound with similar uricosuric but little or no anticoagulant activity Among the 106 coumarin derivatives originally studied by Overman et al (1944) few were effective anticoagulants Special interest attaches to their Compound 16, which was the free carboxylic acid form of ethyl biscoumacetate Unlike the currently used ethyl ester, Compound 16 lacked anticoagulant activity Its renal tubular affinities now require separate testing, with possibilities that are obvious Not only might a useful new uricosuric agent emerge but also (in the light of previous remarks) one with possible antiphlogistic properties as an added advantage in the management of gout

A final reflection concerns uric acid, coronary atherosclerosis, and anticoagulant therapy In an exhaustive study of 100 patients, aged less than 40, with coronary heart disease, Gertler and White (1954) found that serum urate levels were significantly higher than normal. An index derived from serum-urate, cholesterol, and lipid phosphorus provided better correlation with the disease than any other data Logically this implies that correction of moderate hyperuricæmia—even apart from gout—may be no less important, in the prevention or management of coronary atherosclerosis, than controversial attempts to lower the serum cholesterol level.

The use of coumarin anticoagulants in myocardial infarction has been justified mainly by statistical evidence that mortality and complications are reduced (Tulloch and Gilchrist 1951) Though such therapy is currently controlled in terms of blood coagulability, there is no proof that the clinical results are directly due to diminished prothrombin activity The discovery that ethyl biscoumacetate has a distinct additional action on uric acid—a substance implicated independently in coronary heart disease—may widen the present concept of modern anticoagulant therapy

Summary

The anticoagulant drug ethyl biscoumacetate (' Tromexan ') strongly enhances the renal excretion of uric acid in man, rat, and dog This uricosuric action is due as in the case of probenecid, salicylate, cinchophen, and similar agents, to reversible impairment of urate reabsorption by the proximal tubules, with consequent increase of urate clearance In this respect ethyl biscoumacetate appears, from the limited data so far obtained, to have a uricosuric potency at least comparable to that of probenecid

A single oral dose of 1 2–1 8 g of ethyl biscoumacetate is associated in man with a striking fall of serum urate levels and greatly increased urate/creatinine clearance ratios. This effect occurs 1 or 2 hours after ingestion of the drug in contrast to the longer lag required for depletion of clotting factors

The fall of the serum urate level persists during the course of daily therapy with ethyl biscoumacetate fluctuating as doses are changed, but not directly paralleling prothrombin activity The presence of considerable renal disease complicating gout does not abolish the uricosuric action of ethyl biscoumacetate

Ethyl biscoumacetate, like probenecid, enhances urate clearance in the mongrel dog In the dalmatian coach hound which has a reversed tubular transport mechanism for urate, with active secretion in addition to glomerular filtration, both drugs reduce the abnormally large urate clearance

Established uricosuric agents are known to inhibit in various degrees the tubular secretion of a group of compounds using the same transport process as active reabsorption of urate Preliminary data indicate that ethyl biscoumacetate similarly impairs the transport of P.A.H and P.S.P and may weakly affect the secretion of penicillin.

The implications of these findings are discussed. Pharmacological relationships among uricosuric anti coagulant and antirheumatic drugs are examined in the light of the newly discovered action of ethyl biscoumacetate, and the need for correlating their respective biochemical mechanisms is pointed out

Molecular structures determining participation in tubular transport are commented on and the suggestion is made that valency properties associated with tautomerism or with carbonyl unsaturation are as important in cellular reactions as a particular key substituent

Studies of related coumarin compounds may yield a useful new uricosuric agent with little or no anticoagulant activity, for the management of gout

It is interesting that urate has been implicated in coronary heart-disease the uricosuric action of ethyl biscoumacetate gives rise to speculation whether the rôle of coumarin drugs in myocardial infarction is entirely explicable by their anticoagulant effect

We gratefully acknowledge expert technical assistance from Mrs. L. Powell B.SC Miss M Lloyd B.SC Miss D Borcherds, F.I.S.C., and Mr B Todt and helpful cooperation in various aspects of the work from colleagues at Groote Schuur Hospital and the University of Cape Town. These studies received financial support from the South African Council for Scientific and Industrial Research the University of Cape Town Staff Research Fund, and Messrs. Sharp & Dohme U.S.A

DERMATITIS herpetiformis (Dühring's disease) is of unknown ætiology, is characterised by severe itching and grouped vesicles in the skin and persists for many years Its symptoms and signs can be suppressed by certain substances of which the most effective have hitherto been arsenic and sulphapyridine Recently sulphones have been added to the list of such agents

Dapsone (4 4′-diaminodiphenyl sulphone) was first prepared nearly fifty years ago but it was not until 1937 that its antibacterial power was reported by Buttle et al in England and by Fourneau et al in France Rist (1939) showed dapsone to be active both in vitro and in vivo against tuberculosis

Despite these observations dapsone was thought to be too toxic for use in man presumably since it could not be safely administered in the same dosage as sulphanilamide (Francis and Spinks 1950)

This toxicity led to the production of active but less toxic derivatives of dapsone (e g sulphoxone sodium and solapsone) which found a place in the chemotherapy of leprosy (Cochrane et al 1949) When it was realised that the antibacterial activity of these more complex sulphones was due to the liberation of dapsone in the body (Francis and Spinks 1950) there was a return to the use of dapsone itself in a much lower dosage Lowe (1950) had already shown that dapsone in a lower and non toxic dosage was effective in leprosy and since then dapsone has been increasingly used in leprosy

Possibly because of the antibacterial spectrum of dapsone or the apparent resemblance of its structural formula to that of sulphapyridine or its success in leprosy dermatologists began to investigate its use in certain skin diseases (Longhi 1951)

The use of sulphones in dermatitis herpetiformis was first reported by Esteves and Brandão (1950) who recorded successful control in 3 patients with di-substituted derivatives of dapsone (sulphoxone sodium 0 3–0 6 g daily and solapsone 0 5–2 0 g daily) They compared the effects of these two substances and of sulphapyridine in the same patients The patients remarked that control with the sulphones was similar to but rather less perfect than that obtained with sulphapyridine

Cornbleet (1951) reported the use of sulphoxone sodium in the treatment of 13 patients with dermatitis herpetiformis, over a period of up to 2½ years Some of these had previously proved refractory to other therapy, including sulphapyridine All his patients were decidedly improved, or had complete remissions, during the treatment with sulphoxone sodium A transient normocytic anæmia was the commonest side-effect The dosage was 300–900 mg daily, and Cornbleet suggested that "it was the treatment of choice in Dühring's disease "

Since the activity of the more complex sulphones depends on their hydrolysis to dapsone in the body, Kruizinga and Hamminga (1953) treated 12 cases of dermatitis herpetiformis with dapsone They reported that symptoms were controlled with doses of 100 mg daily, and concluded that the effect of dapsone in dermatitis herpetiformis was superior to that of sulphapyridine

Vickers (1954) notes that dapsone has now become the first line of defence in the control of dermatitis herpetiformis Calnan (1954) found that 29 of 30 cases of dermatitis herpetiformis treated with dapsone showed an excellent response, and he concluded that dapsone was preferable to sulphapyridine He stated that it seldom produced toxic side effects in the dosage used He recommended a dosage of 50–200 mg daily but noted that some patients could be kept well with as little as 50 mg on alternate days

After being afforded the opportunity, by Dr H R Vickers and Dr I B Sneddon, of seeing some of their cases treated with dapsone at Sheffield, we became interested in observing the effect of dapsone on patients with dermatitis herpetiformis at this hospital

Material and Method

We report here the results of treatment with dapsone over eleven months in 28 patients with dermatitis herpetiformis There were 20 males and 8 females, aged 18–72, and all had the adult form of dermatitis herpetiformis

The diagnosis was made clinically, and only patients with typical eruptions were included The majority had been under previous treatment with arsenic or sulphapyridine at this hospital for up to seven years, with varying degrees of control Several had had dermatitis herpetiformis for many years before first coming under treatment here Most of them had obtained some useful relief with either liquor arsenicalis minims 3–4 t d s by mouth or sulphapyridine 0 5–2 0 g daily These dosages had been adjusted at intervals to maintain suppression of symptoms, the intensity of which altered from time to time in accordance with the natural variations in the severity of the disease

Usually most patients had started treatment with arsenic when the condition was first diagnosed in the past After a month or so, when some suppression of the disorder was achieved, their treatment was changed to sulphapyridine In none of them had any serious toxic effects been observed with either drug, except that one patient had been unable to tolerate sulphapyridine because it provoked angioneurotic œdema As an indication of changing views on therapy, it was found that persons developing dermatitis herpetiformis in more recent years received less treatment with arsenic than did earlier patients, and latterly were given little or no arsenic at all

Dapsone was substituted for the previous therapy in the present patients primarily to determine if the eruption could be better controlled with dapsone than with previous measures, and was not done because of any toxic reactions with arsenic or sulphapyridine

The dapsone was administered by mouth in a single daily dose of 50–100 mg, varying if necessary according to the changing intensity of the eruption Full dosage was used from the outset Routine estimations of hæmoglobin were made in the early stages of therapy in nearly all cases, and in all at intervals thereafter When dapsone therapy had been used for several months, it was decided to perform also a routine series of liver function tests (comprising estimations of serum bilirubin,

TABLE I—RESULTS OF INVESTIGATION AND TREATMENT

Case no	Previous therapy			Dapsone			Toxic effects	Hæmoglobin (% Haldane)*
	Arsenic (mos)	Sulpha pyridine (yr)	Control achieved	Dose (mg daily)	Duration (mos)	Control achieved

* ——, Hb not estimated

alkaline phosphatase, and plasma protein and the empirical liver function tests—thymol turbidity, thymol flocculation, and serum gold tests) on any patients who had received dapsone for more than two months. All the patients in this series had one such test This was introduced because hepatitis had been reported as a toxic side-effect (e.g Cochrane et al. 1949 Molesworth and Narayanaswami 1952) although Smith (1950) considered that dapsone could not be shown to have any effect on the liver function in a dosage of less than 300 mg daily

All the patients in this series received treatment with dapsone for at least three months The control adopted was that available through the nature of the disease itself which promptly relapsed if the suppressive treatment was omitted or if the dosage of dapsone became inadequate The comparison with any previous therapy was retrospective and based on a clinical appreciation of the condition of each patient This was usually substantiated by the patient's subjective impressions.

In the assessment of the degree of response the following arbitrary standards were selected both for dapsone and for the previous suppressive therapy

Good complete suppression of signs, or with only occasional excoriations, crusted papules or blisters. No itching.

Fair a few lesions most of the time but never severe Some itching

Poor many lesions and much itching

Variable suppression varied between fair and poor" Usually applied to patients who had only taken their suppressive drug irregularly or intermittently

Results

The results of treatment together with the results of routine investigations are shown in table I

Biochemical Investigations

Cochrane et al. (1949) suggested that the skin might have a selective ability to fix dapsone but Smith (1949) Dharmendra et al (1950) Lowe and Davey (1951) and Francis (1953) did not support the hypothesis Nevertheless some workers still felt that selective concentration of dapsone in the skin might take place and could therefore explain the action of dapsone in leprosy and in dermatitis herpetiformis

We therefore felt that an investigation of the levels of dapsone in the blood and skin of some of our patients would be useful, because it might explain the action of dapsone in dermatitis herpetiformis and because of the interest of leprologists in these levels

Samples of blood were taken from 6 patients and paper specimens of skin from 4 patients The method used for determination of free dapsone in the blood was that described by Francis and Spinks (1950)—namely extraction from disodium hydrogen phosphate buffered blood into benzene, transfer into hydrochloric acid followed by diazotisation and coupling to N-β-sulphato ethyl m toluidine Local anæsthetics containing a primary aromatic amino group (e g procaine) interfere with this method because they take part in the diazotisation thus giving rise to figures for dapsone which are much higher than they should be We therefore did the skin biopsies under trichloroethylene analgesia with the Cyprane inhaler before determining the amount of free dapsone in the skin by the same method as described for blood.

Because of the low skin-dapsone level in case 3 it was decided to pool the skin samples from the remainder (cases 4 10 and 15) taking the mean value because this would facilitate the estimation of the very small quantity of dapsone available in the biopsy material

TABLE II—LEVELS OF DAPSONE IN BLOOD AND SKIN

Case no	Blood dapsone (mg per 100 ml)	Skin dapsone (mg per 100 g)	Dosage of dapsone at time of biopsy
3	0·34	0·01	100 mg daily for last 29 wk.
4	0·21	0·13	100 mg daily for last 8 wk.
10	0·27	0·13*	100 mg daily for last 21 wk
15	0·09	0·13	50 mg daily for last 10 wk.
8	0·17	No biopsy	50 mg daily for last 12 wk.
18	0·12	No biopsy	50 mg daily for last 3 wk

Skin samples from cases 4 10 and 15 were pooled

The levels of dapsone found in blood and skin are recorded in table II which shows that there was no selective concentration of dapsone in the skin compared with the blood Since our observations agree with those of Smith (1949) Dharmendra et al (1950) and Lowe and Davey (1951) in man and Francis in animals (1953), we suggest that all the available evidence is against the hypothesis that dapsone is specifically accumulated in the skin

Discussion

Dermatitis herpetiformis is much subject to periodical variation in intensity and tends in some cases to become less severe with the passage of many years For this reason a long period of study is required to establish the true worth of a new therapeutic agent However our early results have been encouraging In 23 of our 28 patients (82%) there was very good control of their eruptions In the remaining 5 (18%) a fair degree of control was achieved

A comparison of the efficacy of dapsone and that of sulphapyridine was possible in retrospect, in 23 patients 8 of these (35%) were very much better when receiving dapsone than they had been with sulphapyridine and a further 2 (9%) had a somewhat greater degree of suppression of symptoms with the newer treatment 12 patients (52%) had an approximately equal degree of control with either drug 1 patient (4%) had obtained better results with sulphapyridine in his case the suppression was 'good' with sulphapyridine but only fair with dapsone

In 5 of the patients no comparison between dapsone and sulphapyridine was possible 4 of them had never received sulphapyridine and 1 had been unable to tolerate it because it provoked angioneurotic œdema Of these patients 3 had received arsenic for short periods The remaining 2 patients had been treated with dapsone from the time of their first attendance

Many patients volunteered that they preferred dapsone to sulphapyridine and found the itching suppressed more rapidly by dapsone However it must be noted that, while receiving dapsone patients may have been kept under a more intense regular and critical scrutiny than they had received previously and dosage levels were perhaps adjusted with greater promptitude as the disease fluctuated

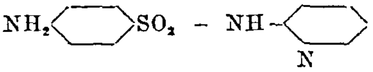
The highest dosage used was 150 mg daily and most patients found 50–100 mg daily sufficient None began treatment with less than 50 mg a day No attempt was made to induce treatment slowly with small initial doses and a gradual subsequent increase to a therapeutic level in the manner recommended by Lowe (1950) However Lowe was using daily doses which were *ultimately* much larger than those used by us

Up to now no serious toxic effects have been observed from dapsone Some anæmia as described by previous workers was observed in 6 cases in the early stages of therapy but was not troublesome and never became an indication for stopping the treatment. In all those in whom the measure was deemed necessary the anæmia responded to iron by mouth 2 patients showed cyanosis in case 24 spectroscopy of the blood showed the absorption band of sulphæmoglobin (though not of methæmoglobin), and in case 6 the cyanosis was cardiovascular in origin and related to auricular fibrillation and hypertension There were no instances of jaundice, and on the basis of liver-function tests we did not obtain evidence of gross liver dysfunction in any patient 2 patients (cases 3 and 4) had moderately raised serum-bilirubin levels, and case 12 showed slight abnormalities in the empirical tests In addition 3 patients (cases 5, 24, and 27) had raised blood-alkaline phosphatase levels No single patient showed any combination of these abnormalities, and usually the departure from normal values was slight The total number of cases in our series is not large, and it may not be wise at this stage to dogmatise on the question of liver damage from administration of dapsone for dermatitis herpetiformis Liver-function tests of the type we applied do not exclude minor degrees of hepatic dysfunction Lowe (1951) has commented that the occurrence of liver damage in patients receiving dapsone may have been related to the fact that they were already suffering from nutritional deficiencies In many cases where jaundice was reported dapsone was being administered in much larger dosage than in our patients However, Howell (1955) reports a possible instance of toxic hepatitis in a woman who had been given dapsone 50 mg daily for dermatitis herpetiformis None of our patients developed a drug eruption or a psychosis while taking dapsone

This absence of serious toxic effects in our series, coupled with the initial full dosage, was one reason why it was suggested to us that dapsone might be selectively concentrated in the skin in dermatitis herpetiformis The result of investigation on this point in 4 of the present patients does not support this hypothesis There was no selective concentration of dapsone in the skin compared with blood-dapsone levels

The good response of patients with dermatitis herpetiformis to dapsone does not so far appear to help towards elucidating the ætiology of the disease Dapsone and sulphapyridine are both merely suppressive agents, and dermatitis herpetiformis relapses rapidly if the treatment is omitted Possibly the apparent likeness between the structural formulæ of dapsone and sulphapyridine may have led earlier workers to use dapsone in dermatitis herpetiformis, which they knew was favourably influenced by sulphapyridine Calnan (1954) has called attention to the similarity of the structural formulæ

Sulphapyridine



Dapsone

It is, of course, possible that the common feature  may have something to do with their action in dermatitis herpetiformis, just as presumably it has in relation to their antibacterial action However, from the chemical standpoint the linkage →C—SO_2—C← of dapsone is very different from the linkage →C—SO_2—NH of sulphapyridine Moreover the chemical properties of the pyridine ring  in sulphapyridine differ radically from those of the grouping  *in dapsone*

The facts that sulphapyridine is the only sulphonamide known to be effective in Dühring's disease, and that this property is shared with dapsone, seem to constitute just one of the many problems of chemotherapy which we ca [illegible] lain, for in our view any resemblance between their structural formulæ is "pictorial" rather tha constitutional.

Conclusions

The degree of suppression of the signs and symptom of dermatitis herpetiformis with dapsone is good and, i this series, tended to be more satisfactory than wit previous therapy

Our experience confirms the impressions of others tha dapsone is the drug of choice in dermatitis herpetiformis Nevertheless 1 patient seemed to obtain better relief with sulphapyridine, and 12 patients had an equal degree of control with either drug For this reason we suggest that sulphapyridine should not be discarded entirely at present

The rapid effectiveness of dapsone in dermatitis herpeti formis and the absence of serious toxic reactions with the dosage used are not explained by any selective concentration of dapsone in the skin

Summary

The results of treating 28 cases of dermatitis herpeti formis with dapsone for three to eleven months are reported

With a daily dosage of 50–150 mg good control of the disease was achieved in 23 patients (82%), and fair control in the remaining 5 (18%)

Comparison with previously administered sulpha pyridine suggested that dapsone was usually the more effective

No serious toxic effects were observed Some anæmia developed early in the treatment in several cases, but there was no evidence of either jaundice or gross liver dysfunction Minor abnormalities were indicated by liver function tests in 6 patients 1 patient developed sulphæmoglobinæmia

A biochemical study in 4 patients with dermatitis herpetiformis showed no selective concentration of dapsone in the skin

Though dapsone now appears to be the drug of choice in dermatitis herpetiformis, sulphapyridine is of equal value in many cases and may be the more effective therapy in a few

The similarity in chemical configuration between sulphapyridine and dapsone is more apparent than real. We feel that this superficial likeness does not explain their comparable ability to control dermatitis herpeti formis

Our thanks are due to the consultants of the Manchester and Salford Hospital for Skin Diseases for permitting us to study and treat the patients under their care, to Dr R G Cochrane, who suggested the biochemical investigations, to Dr R R Goodall, of the I C.I Research Department, who carried them out, and to the patients for their coöperation

DAPSONE IN THE TREATMENT OF DERMATITIS HERPETIFORMIS

J O'D ALEXANDER
M.B Birm. F.R.F.P.S
THIRD ASSISTANT PHYSICIAN DEPARTMENT OF DERMATOLOGY, GLASGOW ROYAL INFIRMARY

Cornbleet (1951) reported encouraging results in the treatment of 12 cases of dermatitis herpetiformis with Diasone' This substance like Promin and Sulphetrone (solapsone) is a substitution product of 4 4 diaminodiphenyl sulphone (dapsone *B.P C*) which has the following structural formula

These substitution products originally introduced because of their supposed therapeutic superiority over the parent substance and because they were thought to be less toxic in fact owe their therapeutic activity to the liberation and absorption of dapsone

Kruizinga and Hamminga (1953) have reported excellent response to dapsone in 12 cases of dermatitis herpetiformis I report here the effects of dapsone in 28 cases

The disease is manifested by an eruption of grouped urticarial papules vesicles bullæ or even pustules which tend to have a characteristic distribution The lesions are commonly found around the elbows over the scapular areas, on the outer sides of the hips across the sacrococcygeal region and around the front of the knees More than one variety of lesion may be present The lesions recur continuously in the same area and are intolerably itchy In most cases dapsone causes complete suppression of itching in a day or two and the lesions clear up within a week Continuation of treatment prevents recurrence Kruizinga and Hamminga (1953) have made it clear, however, that dapsone only suppresses the disease; it does not cure Withdrawal of dapsone leads to prompt relapse The itch usually returns within forty-eight hours and is rapidly followed by a fresh eruption of lesions, which in their early stages tend to be monomorphic—i.e all urticarial all vesicular or all bullous The herpetiform appearance is more often appreciated during a relapse than in the chronic untreated case

Method of Administration

Dapsone is given by mouth According to Smith (1950) the largest tolerated dose, as used in leprosy, is 300 mg daily In the present series the initial dosage was arbitrarily fixed at 200 mg daily for the first week, followed by 100 mg daily for the next two weeks Thereafter the dosage was adjusted to the minimum required to suppress symptoms If the initial dosage was inadequate it was increased to 300 mg daily for a maximum of two weeks and then gradually lowered to the minimal maintenance dose If 300 mg daily did not control the dermatitis, treatment with dapsone was stopped

Results

Of the 28 patients 19 were males The 28 patients were aged 10–86 19 of them being between the ages of 20 and 60 A widespread generalised and often polymorphic rash with much evidence of excoriation was classed as severe there were 6 such cases A moderately severe case was one in which there was an abundance of lesions confined to certain areas of predilection there were 16 such cases The remaining 6 cases were mild with only few lesions in one or more of the characteristic sites

24 cases were successfully controlled and observed for periods varying from nineteen to seventy-one weeks In 4 cases the treatment was stopped without causing an immediate relapse 3 of them have remained clear for fourteen sixteen and thirty four weeks and the 4th relapsed after six weeks, and treatment had to be restarted Treatment was stopped in 2 other cases 1 had a sudden unexplained rise in blood urea level, and the other, aged 86 had a persistent reticulocytosis (10%) In neither case was the treatment recommenced The maintenance doses were

—	< 100 mg daily	100 mg daily	> 100 mg daily
Severe	2	1 (1 remission)	0
Moderate	3	10 (1)	2
Mild	3 (1 remission)	1	2 (1 remission)
Total	8	12	4

The maintenance dose in most cases was 100 mg daily or less, regardless of the severity

Treatment was deliberately withdrawn in 4 cases for a week In several others treatment was inadvertently stopped by the patients for a few days at a time, for reasons such as shortage of supply In every case there was an immediate relapse, which was easily controlled by resumption of therapy as for untreated cases 12 of the cases had previously been treated experimentally with various sulphonamides other than sulphapyridine and with placebos (lactose tablets) All of these cases relapsed under such treatment

Of the 4 cases unsuccessfully treated with dapsone, 3 were severe Partial control was achieved in 1 of these but the maintenance dose required for even this effect was 300 mg daily, and it was felt that this was too large for long continued administration Neither of the 2 other cases nor 1 moderately severe case showed any favourable response to dapsone

Toxic Effects

Benson and Goodman (1945) listed the toxic effects of diasone (which are similar to those of dapsone) The commonest *subjective effects* were fatigue nervousness vertigo headache, and dyspnœa and anorexia, nausea epigastric distress diarrhœa disorientation restlessness insomnia, tremors, *diplopia myalgia* and palpitation also occurred Other workers agree with this list (Pfuetze and Pyle 1945, Floch and Destombes 1949, Cochrane et al 1949, Rist and Cottet 1949) Pfuetze and Pyle add that these symptoms are often aggravated pre existing complaints. Among the objective effects only cyanosis and anæmia are common but agranulocytosis, [illegible] *dermatitis jaundice tachycardia fever*, and enlargement of the thyroid gland have also been reported

In the present series subjective effects were trivial and included dyspnœa (3), tiredness (3), headache ([illegible]) nausea (2) anorexia (1), and palpitation (1)

18 patients were clinically cyanosed (7 severely) Only 2 patients showed a temporary decrease of hæmoglobin of more than 10%, the greatest being 21% In [illegible] patient the blood urea level rose temporarily to 150 [illegible] per 100 ml., it began to fall before the dapsone was withheld The only evidence of liver dysfunction was a temporary increase of thymol turbidity in [illegible] other liver function tests including examination for urobilin were negative (Ehrlich's aldehyde [illegible] urobilinogen is invalidated by dapsone) White [illegible] the leucocyte count was constantly within

Discussion

Dapsone is a potent therapeutic weapon [illegible] of dermatitis herpetiformis It rapidly [illegible] and symptoms and a small maintenance [illegible] keep them in abeyance In this [illegible] sulphapyridine and it is just as [illegible] experience no case which has [illegible] has failed to respond equally [illegible] being smaller, are easier to [illegible] experienced both are in [illegible] dapsone It does not [illegible] depression often caused

drugs are similar also in that neither cures the disease, and withdrawal of therapy usually leads to relapse With both, the maintenance dose may be extremely small one of my patients was controlled with 0 25 g of sulphapyridine daily, and 2 of the present cases needed only 100 mg of dapsone once weekly

Lowe (1952), discussing the use of dapsone in the treatment of leprosy, said that slow induction of treatment with dapsone minimised the risk of acute toxic effects Kruizinga and Hamminga (1953), in accordance with this dictum, advocated an initial dose of 50 mg daily, to be gradually increased until control was achieved The dose was then lowered slowly until the minimum maintenance level for the individual case was reached The method used in the present series, in which I started with a moderately high dose, was devised by analogy with the dosage used in treatment with sulphapyridine My experience with sulphapyridine suggested that an initial inadequate dose often caused difficulty in controlling dermatitis herpetiformis, whereas a short period of initial high dosage rapidly controls the disorder Dosage may then be quickly reduced to the required maintenance level This method seems to work just as well with dapsone Apart from cyanosis, the toxic effects seen were few and very mild and transient This bears out the generally accepted view that patients develop a tolerance to sulphones—a tolerance that does not affect the therapeutic efficacy of the drug but only its toxic effects (Rist and Cottet 1949) Cyanosis must be excepted from this statement

Cyanosis—Several workers are agreed that the degree of cyanosis bears no constant relation to the blood-level of dapsone (Pfuetze and Pyle 1945, Benson and Goodman 1945) This appeared to be true of the 17 patients developing cyanosis in this series There was no correlation between the degree of cyanosis and the dosage of dapsone Unlike other side effects, cyanosis seems to persist indefinitely but is not associated with any subjective phenomena The cause of the cyanosis is undoubtedly the presence of methæmoglobinæmia This has been confirmed in many cases by Dr A G Baikie

Although there was little anæmia in any case, there was evidence of mild hæmolysis in several In 1 case the hæmoglobin was reduced by 24% but was restored without stopping treatment

Control of Treatment—Muir (1950), discussing the control of treatment of leprosy with dapsone, says that "hæmoglobin estimation together with clinical signs and symptoms is a safe guide to the amount of dapsone tolerated" In the present series many other investigations were also made, but the fifteen months' experience of treating dermatitis herpetiformis with dapsone confirms Muir's statement

Summary

The use of dapsone *B.P C* in the treatment of dermatitis herpetiformis is described

28 cases were treated, with excellent control in 24

The toxic effects of the drug are discussed, and requirements for control of treatment are determined

The relative merits of dapsone and sulphapyridine are compared

I wish to thank Dr G Harvey for permission to publish these cases, and Dr Baikie for investigating the hæmatological effects of dapsone

CHEMICAL SKIN SEX IN "OVARIAN" AGENESIS

P E POLANI
M D Pisa, M R C P, D C H.
LATE ASSISTANT TO THE DIRECTOR, DEPARTMENT OF CHILD HEALTH

I A MAGNUS
B A, M.B Camb, M.R C P
REGISTRAR AND RESEARCH FELLOW, SKIN DEPARTMENT
GUY'S HOSPITAL, LONDON

THE name of Turner is associated with the syndrome of dwarfism, webbed neck, valgus deformity of the elbow, and sexual infantilism, though its various components had been recognised by previous workers The syndrome manifests itself almost only in females, but cases of webbed neck and dwarfism have been reported also in males Wilkins and Fleischmann (1944), on the grounds of original observations and previously published cases, showed that the gonads of the female patients were devoid of primordial follicles, and named the syndrome "ovarian agenesis" Similar ovarian maldevelopment has also been seen in patients without the gross malformations described by Turner, of course, sexual infantilism is always present, and dwarfism nearly always. Males with webbed neck and dwarfism always have testicles, though generally they are not quite normal.

By chromosomal sexing of skin (Moore et al 1953) it was shown that the pattern of sex chromatin in females with Turner's syndrome corresponds to that of normal males, and it was therefore suggested that these patients may in fact be genetic males with gonadal maldevelopment and intra-uterine feminisation (Polani et al 1954) The results of independent work done by Wilkins et al (1954) and their conclusions support this finding

Pseudocholinesterase Content

Magnus and Thompson (1954) studied the esterase content of normal skin by essaying manometrically the hydrolytic activity of specific enzymes on individual substrates Thus they showed that biopsy specimens of skin taken from males contain significantly smaller amounts of pseudocholinesterase than do those taken from females, the reason for this was unknown

To clarify the significance of this finding in relation to the absence of gonads, and to obtain further data on the sex of patients with "ovarian agenesis," we estimated the pseudocholinesterase content of the axillary skin of nin patients whose biopsy specimens of skin showed a m[illegible] pattern of sex chromatin (see table) and whose leucocyte whenever examined, showed the same pattern (Davidso and Smith 1954) The diagnosis was made on clinic grounds without gonadal biopsy and was supported by

ANALYSIS OF CASES

Age (yr)	Apparent sex	Diagnosis	Chromosomal sex		Pseudocholinesterase activity (µl of CO_2 per g per hr)

T S Turner's syndrome
O A "ovarian agenesis"—i e dwarfism and minor stigmata but without the grosser malformations described by Turner
Mean value for axillary skin of the patients 1431 ± 110
Mean value for axillary skin of normal males 626 ± 40
Mean value for axillary skin of normal females 1326 ± 114
Mean value for other skin areas of normal males 770 ± 3
Mean value for other skin areas of normal females 1148 ± 34

laboratory findings All values of pseudocholinesterase except one borderline, fell within the normal range for women. The mean of the values was not significantly higher than the mean for normal skin in the area of biopsy

Conclusions

If it be accepted that chromosomal sexing detects the genetic sex of the individual, one can state that the pseudo-cholinesterase content of the skin of these patients was not related to their genetic sex but accorded with their apparent sex Because one measures the enzyme content in a unit of weight of skin differences in skin thickness will cause different amounts of enzyme to be assayed. Therefore possibly the pseudocholinesterase content of the skin of our patients was related only to its thickness which thus would be similar to that of normal females Alternatively, the level of skin pseudocholinesterase *may reflect actual differences in concentration* due to nutritional or metabolic states (Waterlow 1950 Magnus and Thompson 1954) in which case it may be influenced by hormonal balance

We are indebted to Dr P M F Bishop and Dr P R Evans and to Prof F T G Prunty for access to the cases under their care Dr Bernard Lennox for sexing the biopsy specimens of skin and Prof R H S Thompson for his interest and suggestions.

CRIPPLING DYSPNŒA WITH HEALING

A DANGER OF EFFECTIVE CHEMOTHERAPY IN PULMONARY TUBERCULOSIS

S E Slade
M.B Lond
MEDICAL REGISTRAR, WINDSOR CHEST CLINIC BERKS

Since the introduction of effective chemotherapy in the treatment of pulmonary tuberculosis many undesirable side effects have been described (Riches 1954 Dixon 1954 Hughes et al 1954)

My present object is to show that treatment which cures may constitute a greater danger to the patient than the disease from which he has been delivered Three representative cases are reported The first ended fatally the second patient *is a* pulmonary cripple; and the third has made a useful recovery

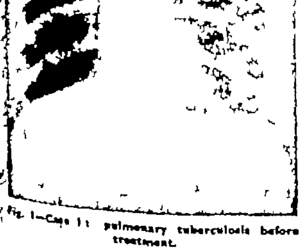

Fig. 1—Case 1: pulmonary tuberculosis before treatment.

Case reports

Case 1 —A woman aged 27 had been diagnosed as having pulmonary tuberculosis nine years previously when she was shown to have widespread disease of the right lung and extension into the left upper zone (fig 1) Sanatorium régime was instituted with a pneumoperitoneum a right phrenic crush, and a left artificial pneumothorax Her sputum remained positive and a right $6^1/_2$ rib thoracoplasty was done three years later The left artificial pneumothorax was abandoned after five years. In September 1954 she was *living at home* cared for by her mother She could manage the stairs between the ground floor and her bedroom unaided but with difficulty Her cough was troublesome and interfered with sleep and she produced 4–6 oz. of sputum daily containing acid fast bacilli. Chest radiography revealed the condition shown in fig 2 Treatment was continued at home with streptomycin isoniazid and *p* aminosalicylic acid After twelve weeks treatment the patient reported that her cough was no longer troublesome her sleep was unbroken for the first time for years, and her sputum *amounted to only* a thimbleful each day In spite of this relief of symptoms she began to be increasingly breathless during the next three weeks even movement in bed distressed her At this stage she had nausea although without much vomiting and all chemotherapy was stopped for this reason but retching continued to exhaust her

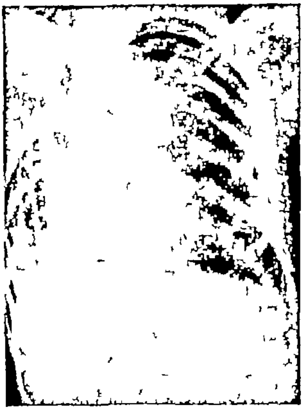

Fig. 2—Case 1: condition of lungs after five years treatment by pneumoperitoneum right phrenic crush left artificial pneumothorax, and right thoracoplasty

On examination she was mildly confused, and there was central cyanosis Speech was difficult because of dyspnœa. She was not anæmic, and there was no deterioration of the physical signs in the chest Her pulse was rapid and thready, there was no peripheral œdema although her neck veins were filled and the liver was palpable but painless Response to digoxin was transitory and she died from pulmonary insufficiency four days later There was no necropsy

Case 2 —A man aged 53 with twenty four years history of pulmonary tuberculosis with positive sputum developed in April 1953 a submucous rectal abscess which discharged through a short direct fistula a year later This was laid open by Mr W B Gabriel in June 1954 Previous treatment had been restricted to sanatorium régime and six weeks treatment with strepto-

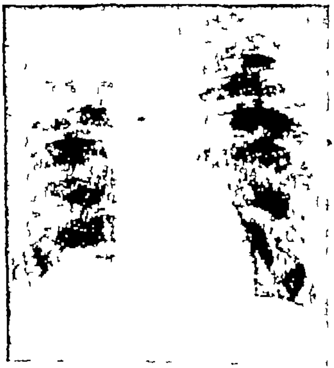

Fig 3—Case 2: condition of lungs after twenty-four years pulmonary tuberculosis.

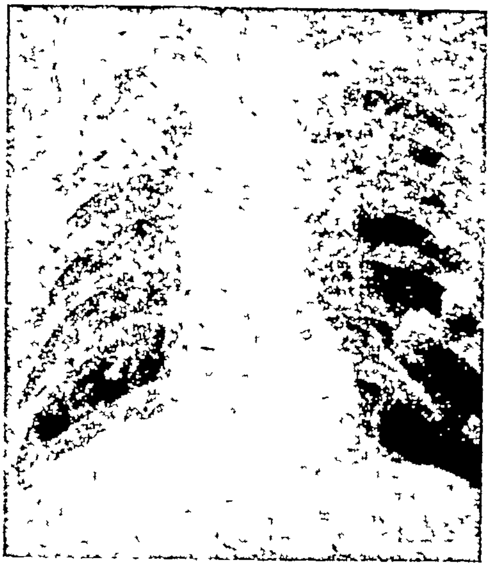

Fig 4—Case 3: condition of lungs after two years' pulmonary tuberculosis

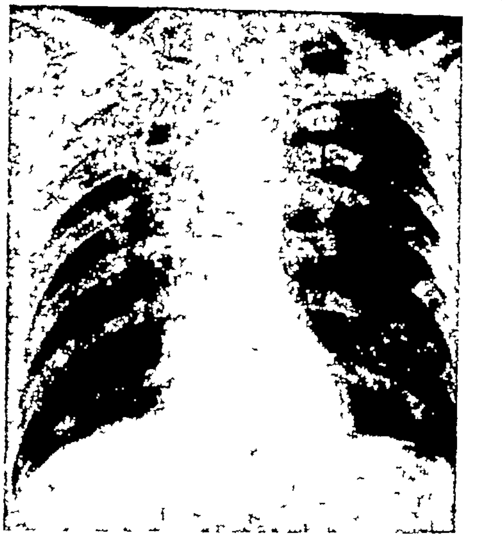

Fig 5—Case 3 condition of lungs after twelve weeks' treatment with streptomycin and isoniazid

mycin and isoniazid Chest radiography revealed the condition shown in fig 3 In September, 1954, tubercle bacilli grown from his sputum were insensitive to streptomycin, and he was given *p* aminosalicylic acid and isoniazid for a year At that time the patient could walk slowly to the village and help his wife in the garden Four weeks after starting treatment he was so short of breath that he could not move about the house unaided He has remained so ever since, although his fistula has healed

Case 3—A male groom, aged 65, first seen in September, 1953, *had two years' history of productive cough, increasing* lassitude, and interrupted sleep He was found to have bilateral excavating disease of the lungs (fig 4) His erythrocyte sedimentation rate (E.S.R.) was 57 mm in 1 hr (Westergren) and his sputum contained tubercle bacilli He could manage the 52 steps up to his living quarters with difficulty

Treatment with streptomycin and isoniazid was started at home Eight weeks later he felt much better, was sleeping well, and managed the stairs as before Radiological improvement was insignificant, the E.S.R. was 32 mm in 1 hr, and the sputum still contained tubercle bacilli Over the next four weeks the patient became cyanosed, very short of breath, and unable to move about his room without help, although his cough no longer troubled him Radiography showed improvement in the lungs (fig 5), and culture of his sputum was negative for tubercle bacilli although a few acid fast structures had been seen on direct smear Treatment was continued, and a month later his symptoms had subsided sufficiently to enable him to manage the stairs once more Since then his chemotherapy has continued to a total of fourteen months, and he has now resumed most of his activities (fig 6) His sputum remains negative for tubercle bacilli.

Discussion

Chronic tuberculosis of the lungs is a host parasite relationship in which the slow process of fibrosis is often compatible with many years of life, during which the persistence of *Mycobacterium tuberculosis* in the diseased tissue delays healing and continues to stimulate the formation of new granulations (Cappell 1951) The abrupt removal of this stimulus by effective chemotherapy may accelerate fibrosis of the diseased tissue (Dick 1954) When the [illegible] is sufficiently widespread, this relatively [illegible], although accompanied by arrest of necrosis, disturbs the remaining lung parenchyma in such a way as to impair pulmonary function The pathology is not clear but seems likely to be compensatory vesicular emphysema of the residual lung tissue

To distinguish patients who will benefit by medical treatment from those who will deteriorate is difficult, simple pulmonary-function tests applied before treatment are unsatisfactory guides because they do not indicate the pulmonary reserve likely to remain when the tuberculosis has been cured

The present three cases suggest that the use of effective antituberculous chemotherapy in widespread chronic tuberculosis may be more harmful than the natural course of the illness

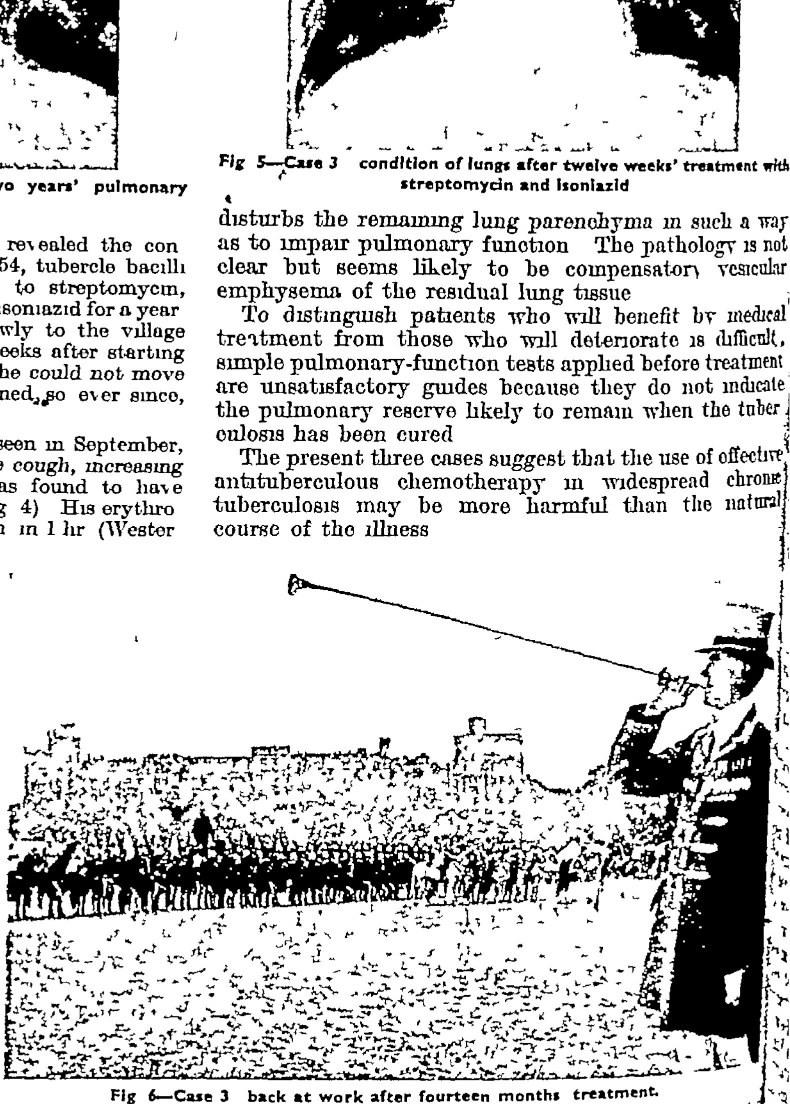

Fig 6—Case 3 back at work after fourteen months treatment.

I wish to thank Dr B C Thompson for permission to publish these cases observed at the Windsor Chest Clinic, Dr E J Holborow for his helpful criticism, and Miss D. Bannister for preparing the illustrations

Medical Societies

ROYAL SOCIETY OF MEDICINE

Juvenile Rheumatism

On May 25 the section of pædiatrics met under the chairmanship of Mr G H MACNAB, its president to discuss Juvenile Rheumatism

Dr BERNARD SCHLESINGER said that thirty years ago every tenth bed at Great Ormond Street was occupied by a child with rheumatic fever now it was difficult to find even enough cases to conduct controlled trials of the newer methods of treatment Medical examinations in L.C.C schools revealed a similar decline in the incidence of rheumatic heart disease over a period of decades In 1947 notification of acute rheumatic fever had been introduced in some regions and in the last seven years such notifications had maintained a steady rate of 0 5–0 3 cases per 1000 population The cause of this decline was no doubt associated with the diminishing incidence of group A streptococcal infections Glover's figures for the parallel fall over eight decades in the death rate from scarlet fever another group A streptococcal disease were very striking Dr Schlesinger recalled how severe some of the acute cases were even twenty or thirty years ago, when heart failure and death were much commoner; but the incidence of chorea had decreased much less There could be no complacency over the present mildness and rarity of the condition Cyclical changes in disease pattern were a commonplace of epidemiology and Dr Schlesinger emphasised that present trends in the natural history of rheumatic fever began long before the introduction of effective antibiotic prophylaxis of streptococcal infections. The change in age distribution was also very remarkable In the '80s the mortality was greatest in the middle aged and elderly, and the disease was primarily one of adults Now the pattern was completely reversed Speaking of ætiology Dr Schlesinger underlined the lack of advance in this field since Dr W R F Collis in Eire and Dr A F Coburn in America had drawn attention to the association with group A streptococcal infections Results of present research in England were interesting and even promising but there was clearly a long way to go before any alternative or adjunct to antistreptococcal prophylaxis was produced

Dr E G L BYWATERS described a joint American and British attempt to assess (*a*) the relative effectiveness of corticotrophin cortisone and aspirin in modifying the course of the acute attack, and (*b*) the relative effectiveness of these three agents in suppressing subsequent heart-disease This clinical experiment was carried out at six centres in Britain and six in the U S.A. Altogether 500 cases, divided into three treatment groups were available for comparison during treatment and follow up The rigid diagnostic criteria for inclusion of cases in the trial and the strictly random allocation of cases to each treatment group resulted in close homogeneity of treatment groups Treatment was given for six weeks The somewhat disappointing conclusions which had so far emerged were (*a*) that on any of the three treatments some fresh manifestations of acute rheumatism developed in some cases although hormones were a little more effective in suppressing the acute attack; (*b*) that rebound phenomena were common after cessation of treatment (*c*) that nodules disappeared more quickly on hormone treatment and (*d*) that there was no difference in heart status between the treatment groups at the present stage of follow up

Dr GERALD THOMAS spoke of the early diagnosis of heart involvement in acute rheumatic fever In his experience the so-called classical signs were often wanting thus tachycardia was unusual except in severe case while cardiac enlargement was rare in the early stage The radiographic appearances of dilatation were due more often to pericardial effusion and he showed radiographs illustrating how effusions occurring early in the acute attack may clear up within a few weeks without residual heart damage Pericarditis occurred in only 15% of cases in the special unit for juvenile rheumatism at Taplow Electrocardiographic abnormalities (prolonged P–R interval, QTC) were found in only a quarter of the cases The significance of soft basal and apical diastolic murmurs and of mitral systolic murmurs had been clarified by follow up studies at Taplow Where loud murmurs were present on admission or developed after admission, follow up usually showed residual cardiac damage Where no clinical or radiographic evidence of carditis was found in the acute attack no cardiac damage was found at follow up In cases where there was minimal evidence of carditis the nature of the murmur was of prognostic significance Dr Thomas drew attention to soft diastolic murmurs developing soon after admission When these were transitory, it was unusual to find evidence of cardiac damage at follow up after three years When these soft diastolic murmurs were constant evidence of cardiac involvement—usually a basal diastolic murmur—was commonly found at follow up Dr Thomas did not think therefore that the transitory mitral diastolic, or Carey Coombs murmur is a precursor of mitral stenosis but rather that a basal diastolic murmur constantly heard is a sensitive index of slight residual heart damage

Dr W R F COLLIS (Dublin) recalled the experiences which had led him twenty five years ago to the view that group A streptococcal infections were ætiologically related to rheumatic fever He was convinced that an antibody antigen reaction was responsible for the rheumatic lesion and on this he based treatment—penicillin to eradicate the infecting organism and cortisone to modify the antibody response and the reaction of the body to its consequences

In reply to questions Dr SCHLESINGER observed that the incidence of rheumatic fever had ceased to drop in 1946 and was now running at a steady low level With regard to prophylaxis he favoured oral penicillin as the safest and most effective agent for preventing streptococcal infections in rheumatic subjects

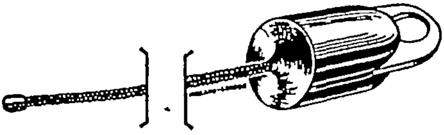
New Inventions

A VARICOSE-VEIN STRIPPER

FOLLOW UPS show that the best treatment to date for varicose veins after ligation of their source of filling (commonly the sapheno-femoral and sapheno-popliteal junction) is stripping out the defective saphenous trunk. The remedy of stripping introduced by Mayo in 1906 and Babcock in 1907, has been resuscitated Myer's stripper is excellent and a modification of it has been used with satisfaction for over a year It has a larger stripping end with a cupped face and key end behind it while its tip is available in several sizes



Modified stripper

The cupped face prevents the stripper from being pulled entirely through a large vein without stripping it or perhaps turning it inside out both of which occur with the Myer stripper The key on the end is to rotate the stripper to and fro, to facilitate its passage along an enlarged vein with pouched varices

I am indebted to Mr Millard for his skill in effecting the alterations

Reviews of Books

Gynæcology

5th ed Douglas H MacLeod, M S, F R C P, F.R C S, F.R C O G, gynæcological surgeon, St Mary's Hospital, London, Charles D Read, M B, F.R C S, F.R C S E, F.R.A C S, director, Institute of Obstetrics and Gynæcology, British Postgraduate Medical Federation, University of London. London J & A Churchill 1955 Pp 864 80*s*

The fifth edition of Eden and Lockyer's *Gynæcology*—the first for twenty years—has new authors but in general retains the form of previous editions Though the style of the text is unlikely to sustain the interest of the more casual reader, the graduate making a special study of gynæcology will find a comprehensive account of the subject in nearly all its aspects, with clear illustrations many of which are new The best sections are those on the more important conditions with which the gynæcological surgeon has to deal—e g, ectopic pregnancy, carcinoma of the uterus, ovarian cysts, and prolapse—and the short operative section is excellent Some topics, however, are covered at perhaps unnecessary length while others get almost cursory treatment Three pages are given to hydatid disease, and two to actinomycosis of the pelvic organs—conditions seldom encountered in this country—whilst only three short paragraphs are given to the common monilial infection of the vagina Further, the accounts of the ætiology, pathology, and elementary bacteriology of various gynæcological lesions are in general extended and elaborated at the expense of clinical features and treatment Thus in a section very properly devoted to appendicitis, there is much on the elementary anatomy and structure of the appendix but only a few sentences on the symptoms, which are described as " those of an acute abdomen, which do not call for detailed description " Sometimes, indeed, treatment is dealt with in summary fashion, and only one opinion is given For example, no more is said about the treatment of carcinoma of the vulva than that " radical vulvectomy with radical excision of the inguinal, femoral, iliac and obturator lymph nodes offers the only prospect of cure The tumours are peculiarly resistant to radiation " While this is a good working rule, the postgraduate might welcome more

The treatment of paralytic ileus is described as consisting in " measures to restore the muscular contractions of the intestine Purgatives, colon irrigation by high enemata, and the use of certain drugs such as acetylcholine and prostigmine, which act powerfully upon intestinal peristalsis, are the methods of choice " Apart from the substitution of acetylcholine for ' Pituitrin,' this statement is what appeared in the 1920 edition of the book, and it is not in accordance with current surgical thought

The detail given on most gynæcological subjects will be useful to anyone who wishes to go beyond the more elementary textbooks, and besides what he is offered here the reader will find helpful suggestions for additional reading

The Visual Fields

A Study of the Applications of Quantitative Perimetry to the Anatomy and Pathology of the Visual Pathways Brodie Hughes, M B Lond, CH M Birm, F R C.S, professor of neurosurgery, University of Birmingham Oxford Blackwell Scientific Publications 1954 Pp 174 35*s*

A comparison with the late H M Traquair's famous monograph is inevitable, and Professor Hughes pays a warm tribute to the inspiration and guidance he has received from it His own book, however, does not attempt to be an exhaustive review of the literature on the visual fields (indeed his references are sometimes less than adequate), and his emphasis, unlike Traquair's, is not on the ophthalmic aspect He deals instead with his own experience as a neurosurgeon, and his clinical observations have clearly been of unusual consistency and accuracy

His book is well arranged written in well-turned English and pleasant and easy to read, yet is crammed with [illegible]trated information The illustrations are clear, the paper good, and the print adequate even for a presbyope It can be strongly recommended, particularly to postgraduates studying for the higher diplomas

The Cerebrospinal Fluid

S Lups, M.D, medical director, Municipal Hospital, Rotterdam, A M F H. Haan, M D, head of the biochemical, cytological and bacteriological laboratory, Sanatorium Orange Nassau's Oord, Renkum Amsterdam Elsevier Publishing Company London Cleaver Hume Press 1954 Pp 350 52*s* 6*d*

This book gains importance because no monograph in English on the cerebrospinal fluid has appeared for some fifteen years In an informative introduction, Dr Pearce Bailey, Bethesda, U S A, gives a historical review, and describes the contributions of the Dutch school, especially of the University of Utrecht, to neurological art and science

The new material—much of it not yet confirmed by other workers—on the anatomy of the meninges and the biochemistry of the cerebrospinal fluid perhaps concerns the neurosurgeon rather than the clinical neurologist The colloidal reactions, which have so far received scant attention in this country, are discussed The potential risks incidental to every arachnoid puncture are underlined, and detailed instructions in technique are given in adults the authors recommend the third, instead of the more usual fourth, lumbar interspace, but point out that in infants and young children puncture should be higher, in the first or second interspace, since the thecal pocket does not descend as low as it does in adults On the other hand, there are some broad unhelpful generalisations.

Thus the section on poliomyelitis states that this disease " can be recognised early from the fluid picture when it *appears that there are fluid deviations,* e g, *pleocytosis,* the administration of convalescent serum is indicated " In point of fact, the diagnosis of non paralytic poliomyelitis, whatever the fluid findings, is merely presumptive until it has been *confirmed by the complement-fixation or kindred* test on paired sera Administration of convalescent serum in this context seems to imply use of the thecal route, though the intravenous route was probably intended (there being serious *objections to intramuscular inoculations* at this stage of the disease) Gamma globulin is now acknowledged to be safer and more potent than convalescent serum but is not without risk if given intravenously, unless well diluted

The translation has perhaps been too literal, and some clumsy constructions have resulted, but the meaning is generally plain The drawings (some in colour and many derived from previous works) are well executed and the numerous graphs clear and simple

---

Genetica Medica (Rome Istituto Gregorio Mendel 1954 Pp 467 L 5000)—This book contains the papers given at the First International Symposium of Medical Genetics held in Rome in September, 1953 The occasion was the official opening of the Gregor Mendel Institute in Rome for the study of medical genetics and of twins. Contributors include Italians, French, Germans, and English, each writing in their own language, and the book provides a useful indication of the centres of activity of medical genetics in Europe In addition, the full text and translations are given of an address by Pope Pius XII, setting out the views of the Roman Catholic Church on the ethical problems involved in advising engaged and married couples who run a risk of having children with a *genotically* determined abnormality

Cardiac Symptoms in the Neuroses (2nd ed London H K Lewis 1955 Pp 50 6*s* 6*d*)—Dr *Doris Baker's* 50 pages of information about the functional cardiac symptoms of left infra mammary pain, palpitation, and sighing respiration are easy to read, and pack in the facts as they are seen and analysed in a cardiac clinic New theories and findings about the mechanisms producing these symptoms are discussed briefly, and there are interesting case histories The little section on management is not encouraging physical reablement and drugs have not proved helpful, and though Dr Baker mentions psychiatry it is without much confidence The best hope lies, she thinks, in getting the patient as fit as possible and helping him to adjust himself to his lot

THE LANCET

LONDON SATURDAY, JUNE 11, 1955

The Outlook for Poliomyelitis Vaccination

Few can have foreseen the consequences of the encouraging report two months ago on last year's trial of poliomyelitis vaccine in the United States. The vaccine was hailed by newspapers as one of the greatest medical discoveries of the century, and the conquest of paralytic poliomyelitis was celebrated. The U.S. Public Health Service authorised the production of vaccine by six commercial firms and relaxed its standards of safety testing. In an incredibly short time an ambitious programme to vaccinate millions of school children this year was well under way. But within a few days there was bad news. A number of children who had received vaccine prepared by the Cutter Laboratories fell ill with paralytic poliomyelitis and the U.S. Public Health Service immediately banned further use of vaccine from these laboratories pending investigations. Figures recently published[1] say that there were 59 cases of paralytic disease and 10 of non-paralytic disease among 400 000 children given Cutter vaccine, and the attack-rate among these children was significantly greater than would have been expected judging from the rates in previous years. In 80% of the paralytic Cutter cases paralysis first appeared in the limb in which the injection was given, and type 1 virus has been isolated from 15 persons who had *poliomyelitis after having Cutter* vaccine. After the early post-vaccination cases there came a sequence of stops and starts in the vaccination programme, coupled with unconvincing assurances that the vaccine was safe and effective and suggestions that some short-circuiting of important controls had taken place. Up to the end of last week a total of 114 cases of poliomyelitis had been reported among vaccinated people, and there had been 60 cases of poliomyelitis, including *42 of paralytic disease, in family* and other close contacts of those who had the vaccine.[2] Of these contact cases 35 (mostly paralytic) were connected with Cutter vaccine. A common sequence of events was a feverish illness or sore throat in the vaccinated child six to fourteen days after vaccination, followed after a similar interval by paralytic or bulbar poliomyelitis in a contact.

That so high a proportion of the post-vaccination cases involved children who had had *one of two* suspect batches means (when considered with the other evidence) that the most likely explanation is that some of this vaccine contained live poliomyelitis virus which had not been completely inactivated by the formaldehyde treatment.[3] But there are conflicting reports of the results of laboratory tests of the Cutter vaccine itself. One report speaks of failure to isolate live virus from the Cutter vaccine,[1] while a second[1] mentions that in one laboratory paralytic poliomyelitis had developed in one of the inoculated monkeys. Most reports state that there is no obvious way in which the preparation and testing of the two suspect batches of vaccine differed from that of other batches from the same or other firms. Faced with this difficult situation the U.S. Public Health Service has made thorough investigations of the methods of preparing vaccine in all six laboratories and after lengthy consultations it has decided to impose stricter safety standards for the manufacture and testing of vaccine. The new standards require, among other things, the presence of a United States public-health inspector in the plant of each manufacturer.[5] The firms concerned, after protesting that the new tests would be too elaborate and costly,[4] have now agreed to the measures recommended, and the interrupted vaccination programme will probably be resumed soon. It is reported that about 70% of the children whose parents had earlier agreed *to vaccination are still* ready to be vaccinated,[4] but the original programme must now be curtailed because sufficient vaccine will not be ready in time.

Assuming vaccine were freely available in this country, what should a doctor say to an anxious parent who asks whether he can recommend this vaccine for his child? Is it safe and will it protect against paralytic poliomyelitis? In the present state of uncertainty he would be forced to reply that there is unfortunately a very small but definite risk that the vaccine may produce paralytic poliomyelitis. This risk may be reduced to something extremely small by the improved tests of the vaccine in tissue-cultures and in monkeys, but there will still be the fear that the tests may not reveal the presence of every live virus particle and that the occasional highly susceptible child may be given the disease by a vaccine which has passed the most rigorous testing. This risk must be weighed against the benefits, which at the moment seem to be a three- or four-fold reduction in the chance of getting paralytic poliomyelitis in the year following vaccination—with presumably some protection for a much longer period, although the extent and duration of this are not yet known. In addition (as we have previously pointed out[6] [7]) there is a risk, of unknown dimensions, that repeated injection of a vaccine prepared from monkey kidney may eventually sensitise the child in some harmful way. This could conceivably have more serious consequences than the accidental infections on which attention has naturally been fixed so far.

What lessons can be learnt from this experience? At least we can now see the danger that lies in publicity, on the modern scale, for a method of prevention or treatment which should still be on probation. We can see that such publicity may force all concerned to apply the method immediately and widely and may leave doctors little opportunity to make up their minds on how to advise their patients. That we in this country were not constrained into premature action was partly perhaps for lack of opportunity and partly because the word poliomyelitis has not yet so menacing a sound here as it has in the United States. In every country—our own included—people are looking to vaccination as the answer to poliomyelitis and all will join in the hope that the present setback may be no more than temporary Something may be gained perhaps from the need to think again. There is as yet no reason to believe that the present vaccine is the most effective which can be produced, and it is possible that, in the end, attenuated virus may prove more satisfactory When the time comes to test this possibility, the happenings of recent weeks should ensure that enthusiasm does not carry us too far before we are ready

Antacids for Peptic Ulcer

IN the absence of firm knowledge about the causes of gastric and duodenal ulcers the medical treatment of patients with these conditions is largely symptomatic The main symptom—pain—is usually at once relieved by reducing the acidity of the gastric contents, and much thought has been given to developing means to this end

Attempts to reduce the concentration of acid secreted have met with indifferent success Drugs given for this purpose have included atropine, methantheliniuim, and propantheline, but their efficacy is questionable An indirect approach, consisting in administration of antacids, is more reliable Patients with duodenal ulcer usually have high gastric acidity, and commonly pain is felt when the stomach is nearly empty In patients with gastric ulcer, on the other hand, the pain is usually felt when the volume of the gastric contents is greater, but the acidity of the contents is likely to be low[1 2] Thus, whether the gastric contents are highly acid or not, the amount of acid to be neutralised at any one moment is likely to be small The patient is usually satisfied to take antacid intermittently, to prevent or control pain, whereas his doctor may wish him to take it continuously, to keep gastric acidity constantly in check Usually the stomach secretes acid continuously throughout the day, and so a single dose of antacid has only a transient action[3] HUNT and MACDONALD[4] found that when the volume of the gastric contents becomes small, emptying is quick, and at the end of an hour only a small proportion of a dose of antacid will still remain in the stomach More continuous action may be secured by an intragastric drip of antacid, but sucking antacid tablets is no less effective, and during sleep the action of a single large dose of antacid may be prolonged by administering a drug, such as tricyclamol, which delays passage of the antacid through the stomach[5]

The ideal antacid should take up acid in the stomach, give it up in the intestine, and remain very insoluble during its passage through the alimentary canal Polyaminostyrene, which is a long chain aromatic base, is one substance that seems to satisfy these requirements but its capacity to absorb HCl is greatest below pH 2 5 and is very small at pH 3 For this reason it does not seem to be highly suitable for use as an antacid, but in Norway some clinicians[6 7] are convinced of its value, and its advantages should certainly be further tested The more usual antacids may be divided into two main classes First there are those—for example, sodium bicarbonate or magnesium oxide—which neutralise part of the acid secreted by the stomach by virtue of their content of potential OH^- ions and thus deprive the body of acid If the amount of acid neutralised exceeds the daily production of metabolic acid the urine will become alkaline, or if the kidneys should fail to compensate completely for the intake of OH^- ions the alkali reserve may begin to rise The seriousness of such alkalosis may have been exaggerated,[8] but there seems to be no reason for using drugs which are potentially dangerous if others equally effective are available Antacids in the second class, such as aluminium hydroxide, do not neutralise the H^+ ions of the gastric secretion, but merely adsorb or buffer them in the stomach and release them in the intestine, where the pH of the contents rises Thus with these there is no possibility of disturbing the *milieu interne* by the addition of OH^- ions Aluminium hydroxide has the additional merit that even in large quantities it will not make the gastric contents more alkaline than pH 7 The optimum acidity for the healing of gastric and duodenal ulcers is not known, but it would seem reasonable to aim for acidities between pH 3 and pH 7, corresponding to less than 1 m.eq of free acid per litre At such acidities the activity of the pepsin in the gastric contents is considerably reduced or is abolished DOUTHWAITE and THORNE[9] found that after ordinary food between 9 and 36 m eq of alkali per hour reduced the acidity of the gastric contents to pH 3 or less, without making the contents alkaline

Buffers, such as aluminium hydroxide, probably have advantages over alkalis, such as magnesium oxide, but the most important practical point is the method of administration Sucking antacid tablets because it continuously controls gastric acidity, greatly preferable to intermittent doses of antacid

Thought for the Patient

THE surgeon who is not concerned with his patients' comfort would be hard to find, it is neverthele profitable to take stock in this matter To ask our selves whether the patient is comfortable is to approach the issue wrongly We pass the bed of a patient who has had an abdominoperineal excision Is he comfortable ? Well, no he has had a big dissection in the pelvis and no better can be expected, besides morphine is giving him relief So run our thoughts as we move to the next bed If instead we ask, "In what way have I caused this patient unnecessary discomfort ?" then the train of thought covers his whole stay in hospital Before operation it was reasonable to submit him to a prick in the finger to make sure he was not anæmic But what of the venesection to discover the state of his electrolytes ? Since he had had no diarrhœa, had not vomited, was taking his food, and was passing urine satisfactorily, may not fashion have dictated this ? True, it only involved the insertion of a needle, but this can cause alarm to some, while others (including some surgeons) prefer pain to the peculiar sensation caused by a needle Investigations exhaust a patient, so the fewer the better, a trip to the X-ray department

is easily arranged but a moment's thought may reveal that the investigation sought will shed little light on the diagnosis or the patient's ability to withstand operation.

Often convention robs us of insight so that we fail to question the value of what we are doing Time was when the bowels were purged as a routine before every operation, fortunately this practice has now virtually ceased But what of pubic shaving ? None will question the need for it before any operation on the anterior abdominal wall, but the pubic hairs are unlikely to contaminate wounds in the perineum, and yet for the patient with piles to be ated or a fissure to be excised they are usually removed together with those at the anal verge ubic shaving is not only acutely embarrassing for any, but a source of discomfort as the hairs grow un. Postoperative pain is directly related to the gree of trauma at operation heavy retraction, nt instead of sharp dissection, suturing under nsion—all these enhance discomfort How often we do all we can to avoid them ? Because time often against surgeons pushed by long lists and gthy operations small insults to human tissue y pass unheeded WILLIAMSON,[1] when removing eptic appendix, tried the exasperating experiment avoiding unnecessary trauma the operation took hour and twenty minutes, but the patient had so le discomfort that she insisted on returning to rk on the fourth day Anæsthesia is doubtless ier to control through an endotracheal tube, ich may therefore be used more often than is ictly necessary even though it leads commonly soreness of throat and sometimes to hoarseness voice Then again, the clips which fasten towels skin on occasion cause more discomfort than the ound itself To the surgeon the position of the tient on the table is of paramount importance, t the position for the best access and exposure y not be best for the patient The gall bladder n be removed from the deepest abdomen without orting to the bridge which hyperextends the ne and causes considerable backache later, and e deep Trendelenburg position, beloved of pros ectomists and gynæcologists is a positive danger arteriosclerotic patients

Why do we allow tradition still to dictate to us a tourniquet shall be placed at the end of the d of a patient whose leg has been amputated ? ondary hæmorrhage after this operation is now eard of and displaying the instrument can only e disturbing thoughts in the patient's mind t perhaps we err most when we have recourse parenteral fluids Gastrectomy completed without ident and with reasonable expedition leaves the tient so little disturbed as to need no intravenous boost' and fluids may be given by mouth within lve to twenty four hours but all too often an travenous infusion is started for the surgeon's the anæsthetist's comfort of mind How often, o, does the house surgeon cut down on the saphenous in regardless of the disability which sometimes ues, because it is easy to find or deprive the tient of the use of his right arm, simply because t has not had the foresight to choose the left for needle or cannula—and then place the whole arm in a splint, with the elbow in extension, l not arranged the apparatus so that the be inadvertently displaced ? The heinous offence using a vein in the cubital fossa is still committed (for this one senior physician used to fine his house-physicians ten shillings) When using blood our responsibility is not only to the patient, the donor should also be borne in mind Before central blood banks were started extravagant use of blood was less likely because donors had to be bled at hospital they came to our aid and were under our care Now no-one at the hospital meets the donors or has to bleed them Suppose that before a major operation three pints are ordered, just to be on the safe side It turns out that only one is needed, and two remain in the refrigerator It may be possible to use these another day—or it may not Yet to give this blood two volunteers have suffered personal inconvenience and even discomfort Letters posted in London during the month of May bore the cancellation mark Blood Donors are Still Urgently Needed

Annotations

THE STORY OF THE R S.M

IN a broadcast on May 29 Mr Donald Boyd[1] said that we English are never so English as when we are pursuing a poetic idea and added that in his opinion we are, in this day and age doing exactly that Dr Maurice Davidson, author of the official history of the Royal Society of Medicine[2] writes on the other hand, of the hard material world of today, when so much that is worth preserving is being jettisoned in the name of progress' He then settles down to describe with much spirit the pursuit of another poetic idea—that of founding a society which should embrace all the specialist societies of medicine It is a story which he notes "abounds with examples of the frustration of useful and necessary reforms by an apotheosis of outworn traditions' but he leaves his readers in no doubt that the outcome was favourable the right traditions jettisoned and the necessary reforms achieved

He takes us back to the time when Dr James Sims sat in the presidential chair of the Medical Society of London for twenty two years so much to the annoyance of more liberal minded members that twenty-six of them resigned in a body and formed, in 1805 at the Freemasons Tavern the Medical and Chirurgical Society of London These founders of the parent body from which the Royal Society of Medicine springs were a distinguished company among them being Abernethy, Baillie Cooper Marcet Saunders, and Yelloly—the last three of whom were the moving spirits in the new venture They used to meet at the Crown and Anchor until they were able to rent no 2, Verulam Buildings, which housed them for four years. After that they had various addresses in Lincoln s Inn Fields ; but in 1834 just as they received their Royal Charter from William IV their pilgrimage towards Wimpole Street brought them to 53 Berners Street and there they settled down for over half a century The Pathological Obstetrical and Epidemiological Societies met in the same street and in 1860 the Royal Medical and Chirurgical Society suggested they should all join together as one society with various sections Nothing came of this ; but in the years which followed the various societies including the Medical Society of London performed a kind of lobster quadrille some advancing, some retreating, to the tune of "Will you, won't you?"

[2] The Royal Society of Medicine The Realisation of an Ideal 1805–1955 Published by the Society at 1 Wimpole Street London, W 1 1955 Pp 201 £1 1s

In 1899 the Royal Medical and Chirurgical Society removed itself to a new house in Hanover Square, and perhaps this change, coupled with the stimulus of a fresh century, encouraged all the societies, at a conference held in 1904 at the Royal College of Physicians, to pass a resolution declaring that an effort to unite them was "highly desirable" In 1905 the long courtship was honourably concluded, the deed was done, and the various societies were united as the Royal Society of Medicine—all save one The Medical Society of London, despite its protestations of approval, in the event preferred single blessedness As Dr Davidson puts it, thus, "the oldest of the London associations of this character remains today an honoured but an independent body" Perhaps (though he does not say so) the outspoken decision of the newest society to admit women as well as men was too much for so determinedly womanless a body as the oldest

The fifty years which have passed since then have seen the steady growth, in prestige no less than size, of the Royal Society of Medicine The building at 1, Wimpole Street, opened in 1912, was enlarged in 1953 by the addition of the present fourth floor Dr Davidson tells of the founding and expansion of the famous library, the gift of the Wellcome Research Library, and the development of the photographic department which now produces microfilms, photocopies, lantern slides, X-ray reductions, prints, photographs of patients, and photomicrographs for doctors in all parts of the world He has much to say of the men who helped to establish the library, especially Sir John MacAlister "whose name and achievements seem to have run throughout the story, like a *leitmotif*" MacAlister's portrait, reproduced in the book with that of many others of the society's worthies, may not be familiar to some fellows, being hung remotely on the third floor MacAlister (a brother of Sir Donald of the General Medical Council) had been obliged by ill health to give up his medical training, and instead trained as a librarian He became the principal resident officer of the Medical and Chirurgical Society, and played a great part in bringing about the union of the societies He started the library, edited the *Proceedings*, and promoted the Fellowship of Medicine, and Dr Davidson believes that the society probably owes more to him than to any other who has worked for it Nevertheless he gives due honour to the other great names, and includes a short account of every president In one particular, however, he disappoints the reader he does not disclose the identity of the "Robert Barnes" who gave his name to the society's principal hall—a puzzle which has teased many a member

In commemoration of its 150 years' of life, first as the Royal Medical and Chirurgical Society, and since as the Royal Society of Medicine, the society held an anniversary dinner on June 7, at which the Duke of Edinburgh received the honorary fellowship and was presented with a specially bound copy of Dr Davidson's book

ORBITAL RADIOGRAPHY

ORBITAL tumours are an important diagnostic problem, for if untreated they inevitably damage the optic nerve and eventually disorganise the contents of the orbit Because of their varied origin—from within the orbit itself, from the paranasal air sinuses, or from the intracranial cavity—the clinical manifestations differ widely in the early stages when a timely operation may preserve vision At this time the tumour often presents an inconclusive picture to the rhinologist, the ophthalmologist, or the neurosurgeon, and the need for some reliable method of localisation is clear Simple radiography of [illegible] it is seldom informative, and from time to time [illegible] unig and Herrenschwand in 1927 first described the technique of injecting air into the episcleral space, efforts have been made to delineate space occupying lesions in the orbit radiographically by injecting contrast media

Cowie and Groves [1] have now found that the best contrast medium is diodone, which is readily soluble, permeates the orbital tissues, provides good contrast, and is not highly irritant Experiments on the cadaver showed that the fluid could be injected so as to fill the episcleral space, the muscle cone, and each of the four quadrants comprising the peripheral surgical space which surrounds the muscle cone, and repeated trials led to recognition of a typical normal appearance when this space is displayed radiographically In further experiments with a preplaced "tumour" of injected cocoa butter a filling defect appeared

17% proved the lowest concentration of diodone that produced reliable radiographs, and this strength (with 4% novocaine as diluent) has been used in 4 cases of orbital tumour In each a filling defect was demonstrated The reliability of this finding has been verified surgically in 1 of the cases, in 2 others the radiographic finding supports the clinical diagnosis, and in the 4th the tumour outlined in the radiographs is to be treated surgically

Experience with this method is still slight, but it may prove valuable for localising not only orbital tumours but also (judging by the experience of Cowie and Groves) certain types of intra ocular foreign body

UTERINE ACTIVITY AND ELECTRICAL RESPONSE

IN the ten years since Dill and Maiden [2] reported their observations, interest has grown in the possible clinical value of records of the electrical activity on the abdominal surface immediately over the uterus during parturition This activity consists in a fluctuating potential with mixed rhythms of shorter duration than that of the uterine contractions Potential differences of 3–10 millivolts are present, and in general the amplitudes are greater during contractions Halliday and Heyns [3] have studied these electrical changes in over 500 patients and have reached some quite unexpected conclusions The conclusions are based on statistical averages, but significant χ^2 factors indicate that the recordings could be used with 95% certainty in the diagnosis of certain conditions

Their findings, they say, provide "some support to the theory that the potentials being observed are an indication (even if indirect) of the expenditure of physiological energy in the process of labour Therefore, it is possible to suggest that when no potentials are observed the patient is not in true labour, and that the contractions will not produce dilatation of the cervix, even though the abdomen is hardening rhythmically" They find no relationship between electrical intensity and length of labour, but they do find a significant connection between such intensity and the rate at which a patient becomes exhausted

That electrical activity should be proportional to progress in labour and not to the rise and fall in uterine tension is surprising, but Steer in the U S A came to much the same conclusion It is known that a single smooth-muscle cell exhibits a change in polarisation concurrent with isometric or with isotonic contraction Moreover, large electrodes placed on the exposed uterus or on isolated strips of uterine muscle collect potential charges concurrently with general or local contraction In such cases anoxia or oxytocic drugs increase the electrical activity The electrical rhythms are rapid and resemble those found on the abdominal surface by the electrohysterograph

3 Halliday E C, Heyns, O S *J Obstet Gynaec, Brit Emp* [illegible] 62 165

If the changes recorded by the electrohysterograph are not due to uterine contractions per se to what do they owe their origin? Halliday and Heyns suggest that they may be related to the chemical changes associated with anoxia but anoxia is often present when there is no progressive labour Alternative explanations are (a) that they are due to a pain reflex (conscious or unconscious) with vasomotor changes in the skin (b) that they are of uterine origin and are present in the skin in sufficient intensity for measurement only with very strong contractions (c) that they reflect uterine retraction, about which little is known When more has been learnt about the cause of these changes the electrohysterograph may win a place in the diagnostic routine of the labour ward.

THE INFANT'S PHYSICAL ENVIRONMENT

THERE is still much uncertainty about the optimum environment for the young infant and his response to either hypothermia[1] or over heating This uncertainty is particularly great in the case of prematurity Here animal research is of limited value since immature animals almost invariably succumb But in their brilliant work on retrolental fibroplasia Ashton and his colleagues[2] made use of the relative immaturity of the newborn kitten's eye to demonstrate the effects of exposure to high oxygen concentration In studying the very young the veterinary surgeon with larger litters and quick turnover has many advantages over his pædiatric colleague and his observations often have a bearing on problems of *infant management*

The neonate can undoubtedly withstand a degree of anoxia that would be lethal to an older child and this, together with his surprising resilience after surgical operation has led to a change in outlook Whereas our predecessors literally wrapped him in cotton wool the new generation tends to believe that he can stand almost anything. But his survival does not necessarily mean that he has passed through an experience unscathed

Kahn and Walker[3] studying African infants, showed that sweat secretion was impaired in those with malnutrition, and that in hot weather this impairment might be associated with fever They exposed infants with kwashiorkor and healthy controls to conditions of heat and humidity such as are found in the poorer African dwellings in hot weather, and determined the response of the sweat glands quantitatively In the malnourished babies the degree of œdema was not strictly related to diminution of sweating but their ability to secrete sweat returned with improved nutrition The findings of Kahn and Walker are supported by the veterinary experiments of Clark and Quin[4] who studied the heat regulating mechanism in merino sheep They found that food intake had a direct effect on the sheep's ability to maintain body temperature during exposure to cold response to hot environment also depended largely on general body condition thin sheep on a poor diet showed suppressed panting reflex and excessive rise in temperature Bower[5] studying the peripheral vasomotor control in healthy children showed that even in normal full term neonates the rise in skin temperature in the other limbs on immersion of one limb in hot water followed a curve different from that obtained with normal infants over three months of age In the very young baby the response was much more sluggish and in almost every case the maximum skin temperature was lower

These reports teach a useful lesson—namely that the neonate is delivered to us at body temperature but is handicapped by poor vasomotor response and a relatively large surface area If he is premature these handicaps are exaggerated With satisfactory feeding each day that passes sees further adjustment to the new environment but even in later infancy the relative instability of the young child may be made evident again by illness infection or malnutrition

THE SOLITARY PULMONARY NODULE

THE widespread use of chest radiography has led to increased interest in the isolated pulmonary nodule unassociated with symptoms[1–10] and Wilkins[11] has now analysed a series of 77 such cases 27 proved to be primary pulmonary carcinomas 6 metastatic carcinomas 18 tuberculous lesions, 21 benign tumours or cysts, and 5 inflammatory processes of various kinds

When an isolated nodule is found the pressing question is whether it is a primary pulmonary carcinoma, because if it is, delay in diagnosis may cast away the possible chance of survival offered by resection In patients below the age of 30 carcinoma is unlikely the chances increase with advancing years, and in Wilkins's series 50% of the lesions in patients over 50 years were proved to be malignant Tuberculosis is commoner in younger patients, but is by no means rare even in the aged Simple cysts and tumours may also be discovered at any age and although some of them have favourite locations in the lung fields this is an uncertain guide because carcinoma may originate in any site Areas of calcification in the lesion (sometimes demonstrable only by tomography) suggest a tuberculoma or hamartoma, but a carcinoma may arise in or near a calcified scar Such generalisations are therefore of limited diagnostic value and a more direct approach is often equally unrewarding The lesion is usually beyond bronchoscopic vision and the finding of no tubercle bacilli or cancer cells in the sputum and bronchial secretions does not help in diagnosis. If the lesion is near the pleura aspiration biopsy may seem the easiest way of resolving doubt but this investigation is best avoided because of the danger of implanting malignant cells in the needle track Inquiry regarding previous radiographic examination of the chest may be more rewarding than elaborate investigations for the recent appearance of a lesion—particularly in an elderly man—has a sinister significance In the majority of cases exploratory thoracotomy is necessary for exact diagnosis and since the risk is trifling compared with the danger of temporising with a possible bronchial carcinoma Wilkins and all others with experience in the subject urge that this operation should be done without delay Naked-eye inspection of the nodule or examination of frozen sections will determine its nature, and thus the extent of operation Even if the lesion turns out to be non malignant most would agree that it will have been 'nane the waur o' a hangin' although many would nowadays be satisfied with probation for a tuberculoma in a young patient

Special Articles

THE HANDICAPPED ADULT IN THE COMMUNITY *

J B M Davies
M.D Lond, D P H
DEPUTY MEDICAL OFFICER OF HEALTH FOR LIVERPOOL

When the handicapped child leaves the care of the local education authority his future is considered by the employment officer, usually with sympathy but seldom in cooperation with the school medical officer Yet decisions must be made at this stage which will decide the child's whole life, and it would be logical for his teachers and the school medical officer, who have steered him through school life, and also the welfare officers who will have to help him later, to be consulted

Basically the problems of the handicapped are medical, capable of true understanding only by doctors, and this is recognised while the child is at school It is the school medical officer, and not the educationalists, who decides whether a residential or day school, a special class or home teaching, is the answer to the child's problems It is the more surprising, then, that the handicapped adolescent does not always continue to be handled by doctors His handicap is unchanged, and his problems are increased as he tries to adjust himself to his new way of life But at the time when there is greater need for medical control, that supervision is relaxed and often removed

Under most large local authorities the medical officer of health is also principal school medical officer, and this ensures that the preschool child's welfare is integrated with that of the school child It is less usual for the M O H to have charge of the welfare services, but, where he does, he and his staff can continue to supervise the handicapped child's life after he leaves school

Even where local administrative arrangements do not favour this cohesion, I believe that each handicapped child—particularly the physically handicapped and delicate children—should be individually considered at the age of 11, when he starts his secondary education, by a panel of his teachers, the school medical officer, the employment officer, and the welfare officer

The Right Job

The chances of success in a job depend on the attitude and character of the handicapped person, on the degree of handicap, and on the energy and approach of those who have to help him Often success is attained only by ingenuity and improvisation The seriously handicapped sometimes achieve great success, while others with minor handicaps fail But, irrespective of the type or degree of handicap, an individual assessment is necessary, and this can only be properly carried out by someone who visits the handicapped person at his home to see the conditions under which he must live

Who should do this assessment? Usually in the case of the blind, and the deaf and dumb, the visit is paid by someone with experience of dealing with the particular handicap With other handicaps the welfare visitor or health visitor carries out this work, often with the help of a hospital almoner, and I can see few drawbacks and many advantages in using general visitors for this purpose, at any rate in the first instance A specialised worker can be consulted later if need be By using general welfare visitors, it should be easier to ensure that the handicapped are being treated as nearly as possible as normal individuals, and more uniformity of treatme between different groups of handicapped people could maintained

Sheltered Workshops

For many of the handicapped—too many, in my vi —jobs will be found in sheltered workshops Becau costs are rising, many of these workshops are facing crisis

The main reasons for rising costs are increased wag and increased competition This latter problem is ve interesting, for it shows one of the fundamental wea nesses of the present workshop system The difficulti of the workshops of the blind are typical of many sheltere workshops today

The trades practised by the blind are traditional- basket-making, mat-making, brush-making, and machin knitting Most of them were selected at the beginnin of the century, and few have been added Yet workin conditions in open industry during this period hav changed radically For instance the cheapest brushe are now machine-made and their quality is as good a and often better than, that of hand-made brushes. It i impossible for any blind workshop to compete wit machine-made brushes, and to sell their products the may have to do so at a loss

A new entrant into a workshop is patiently taug his trade Once he is fully trained, he is accepted as worker in that trade for the rest of his working lif which may be for the next forty-five years If, durin that period, his trade becomes out of date (as has ha pened with hand brush-making) he has to continue i an out-of-date trade, or else try to learn a new one T a severely handicapped person, this may be difficul and no public body likes to put him off work just becau his trade is out of date He usually carries on his trad and through no fault of his own, continues to add to t financial burdens and difficulties of the workshop Fe would wish to disturb any blind worker who has be working satisfactorily for many years at brush mak even if this is now unprofitable; but it is wrong not face the fact that the present system is at fault A fi step should be to stop anyone else being taught t unprofitable trade, but even this has not been accep throughout the country

No one can say for certain whether or when an occup tion suitable for a handicapped person today will n become out of date Where, then, is the answer to th awkward question?

It must be recognised that any sheltered worksh however efficient, will run at an increasing loss Th being so, an even smaller proportion of the disab should be sent to them—not only because of the expe (though it is no use pretending that expense can ignored) but because they will never provide the answ to the main problems This in my view can be found o in open industry At present the handicapped entra into industry, after an initial training, has to pull weight in competition with other workers Each is plac with great patience on the part of the placement office naturally careful selection has to be ensured, and the who are successful in open industry are the happiest handicapped workers The main difficulty in industr placing of a handicapped class is not so much that suitab *occupations are not available*, as that initially th employer cannot afford to employ them The difficulty is met in sheltered workshops, and it is o by considerable augmentation that any workshop ca continue The obvious answer seems to be that augmen tation should be introduced into open industry Toda in Liverpool, for instance, each worker in one of o workshops for the blind costs over £5 a week If w could go to prospective employers in open industry, a offer to augment up to, say, £2 a week, I believe placements would be numerous enough to solve a su stantial part of the problem Of course there are di culties—the complaint of unfair competition, for example But none of these are insurmountable Only a small number of people are involved, and a few industrial firms have already shown that severely disabled persons can do efficient work

---

* B[illegible]d on a paper given to the Society of Medical Officers [illegible] th on Nov 5, 1954

Even if such a suggestion were accepted, there would still be a place for sheltered workshops. But their numbers should be kept to a minimum and they should cater mainly for two groups

(1) Severely disabled whose only hope of full time employment is in sheltered workshops. This should be a small group and should not contain people unable to work full time

(2) A less severely disabled group who are training to enter industry A reasonable time-limit must be placed on their stay and they should not be allowed to drift into the first group.

Those who are in charge of sheltered workshops complain that they are unable to find suitable new skilled trades. But there is another approach to this subject which seems more promising Most of their difficulties arise from competition, which may make a trade hitherto lucrative to the handicapped no longer so attractive The only way to avoid this is for workshops not to be tied to skilled trades at all The Tuberculosis Colony at st Barrow successfully employs handicapped persons in any suitable unskilled work which is available at the time Packing components in tropical packs and dismantling out-of-date wireless equipment have provided work for many years They are prepared to do work for which there is demand at that time and by not tying themselves to any fixed trades they avoid the snags and difficulties of any occupation becoming obsolete

At first sight this may seem a retrograde step for it would deprive the handicapped of the opportunity to learn a skilled trade But this is not so With a larger and larger proportion of the handicapped finding a place in open industry all these would have a skilled trade in industry Those doing the unskilled work would be the few who are employed full time in the workshops, and the real security of these workers is the sheltered workshop itself rather than the occupation they follow

Home Workers

The schemes for home workers vary greatly but since new scales were agreed to two years ago there has been greater uniformity in the system of augmentation These schemes, which are only for full time employment at home, are the only form of sheltered employment open to handicapped people living in rural areas or within small communities where it is impossible to run a workshop

The usual way of assessing full time work in these schemes is to prescribe a minimum amount of work which must be completed by each worker to qualify for augmentation It was a real advance when this system was adopted nationally in preference to the method of fixed augmentation, paid irrespective to output Many of the home worker schemes are not anything like so costly as sheltered workshops and they are working satisfactorily in country areas

The arguments for preferring open industry wherever this is possible still apply to this group, but undoubtedly home worker schemes will always be needed. Perhaps the greatest dangers of these schemes is that augmentation may be offered to part-time workers which would upset the whole concept of augmentation By ensuring a reasonable minimum output of high quality goods this difficulty can be avoided

Occupational Therapy

Part time work comes really into the sphere of occupational therapy Some authorities have set up a domiciliary occupational therapy service The ideal system arranges for occupational therapy to be available to as large a group as possible, including chronic sick and crippled at home those rehabilitating at home after a long illness such as pulmonary tuberculosis and the aged living in their own homes or in hostels

Such a service to be successful must have a satisfactory outlet for the sale of the goods made This problem common with all home made products is best solved by using one central shop to cater for all of them

The advantages of an occupational service are great for not only does it help and encourage many who are beginning to face the problem of overcoming their disabilities but also it is a useful link with the hospitals. Too many patients receive great help from occupational therapy while they are patients, but cease to do so on discharge The domiciliary occupational service should come into action as soon as the patient leaves hospital

Welfare Services

The young crippled adult without a home and in need of care and protection is one of the most pitiful objects today There are a few outstanding voluntary homes but unless a place in one of these can be found, he must be put in part III accommodation intended for aged people

If we are to provide a real welfare service for this group we must take over where the special school leaves off The special training colleges, such as St Loyes at Exeter, should be increased, but there should be one coördinated policy for each handicapped person If possible a decision should be made early in the child s life What is really needed is the kind of supervisory control at present exercised over the handicapped child at school The larger local authorities could provide hostels run in close association with the special schools and special training colleges

However their future is settled the welfare services will continue to play a large part in the lives of most handicapped people At present these services are very unevenly distributed Thus the welfare services for the blind have dwarfed all other welfare provision for the handicapped with the possible exception in some areas of provisions for the deaf and dumb Though the need to extend our welfare services to other groups is nowadays recognised the cost of blind welfare has in fact risen since 1948 proportionately far more than the costs of any of the new welfare services for the handicapped. In Liverpool in 1949 £9397 was spent on the blind against £6419 on the deaf and dumb the physically handicapped, and the epileptic but in the year ending March 31 1955 £25 156 was spent on the blind and £14 041 on the deaf and dumb the physically handicapped, and the epileptic—an increase of 168% for the blind compared with 128% for the other groups

There is also considerable inequality in the standard of service available at different periods of the handicapped person s life For the handicapped school-child, amenities are better than they are at any later time. To lavish all the special care of a residential special school on him and then to provide next to nothing when he leaves school is surely to have failed to understand the meaning of education

What is needed is a steady coördinated policy from school life into adolescent life and on into adult life Many of the severely crippled will not succeed unless they have help at every stage and they will very seldom get it unless the same person, administratively is watching over them all the time My own belief is that until the welfare services are everywhere organised by the medical officer of health the provisions for the adult handicapped will remain as disjointed and haphazard as they are in many parts of the country today

FOOD IN MENTAL HOSPITALS

D G Harington Hawes

SECRETARY, HOSPITAL CATERING AND DIET COMMITTEE,
KING EDWARD'S HOSPITAL FUND FOR LONDON

The tradition that mental patients need only one substantial meal in the day, and that most of them are oblivious to what they eat or how their food is served, dies hard Because of this belief the kitchens of most mental hospitals were designed, equipped, and staffed to provide a simple, inexpensive, repetitive diet, planned round a two-course hot meal at midday Reliance on patients for much of the kitchen work affected not only the standard of cooking but also the type of equipment—hence the outsize boiling pans and banks of steaming-ovens that are still to be found in many a mental hospital kitchen

Today even the most progressive and diet conscious mental-hospital management committee may well be at a loss as to how to proceed Among the obstacles to good catering confronting them may be a badly designed, ill-equipped kitchen serving 2500 meals at midday , unsatisfactory means of distributing food to the wards, aggravated by long hauls out of doors to distant villas and the absence of lifts in multi-storey blocks , ward or villa kitchens that are inadequately equipped and too cramped for a proper service of meals , shortage of trained staff in the main kitchen, coupled with a decline in the proportion of patients available for work in the kitchens , and as a final straw, a chronic lack of money for the catering department

COOKING AND SERVICE

Since the majority of mental hospitals—31 out of 47 in the four Metropolitan regions—have more than 1000 beds, and since most (if not all) of them prepare the main meals for both patients and staff in a central kitchen, it follows that very often upwards of 2500 and even 3000 midday dinners have to be cooked in the same place and at the same time Now it is generally recognised that even under favourable conditions, with good equipment and competent staff, the maximum number of meals which can be cooked in a single kitchen, without deterioration in the standard of preparation, palatability, and nutritive value, is in the region of 1500 Furthermore, in a large hospital kitchen there is the added complication that the bulk of the meals must be ready for distribution simultaneously and at a fixed time This cannot be achieved unless the preparation of some of the components of the meal is started long in advance, with all the spoiling of the food that this entails

DISTRIBUTION

When the moment for distribution comes, new difficulties arise In many mental hospitals the food is loaded into metal containers, which may or may not be insulated but which certainly are not pre-heated These containers then have to be transported to the wards, which may be in blocks or in villas Some will be a long way from the kitchen, and by the time the food has reached the ward half an hour or more may have elapsed In many hospitals the conveyance of the containers to the wards is also a problem , they must either be pulled on trolleys through the hospital grounds to the villas, or man-handled up awkward stairs to upper storey wards Even where adequate electric power is available in the kitchen, the use of pre heated electric trolleys with fitted containers is not necessarily an ideal solution, if only because of the large numbers involved The standard trolley of this kind is reckoned to carry enough food for 30 persons , so a hospital with 2000 patients will need 66 trolleys The difficulty of st nd loading such a fleet of trolleys in one kitchen comment

SERVICE

When the food takes a long time to reach the ward it may have to be warmed up, and this means delay extra work, and some loss in food value In many ward patients take their meals in a dining room or day room which is usually near to the ward or part of it Th charge nurse who has to reheat the food for 40-5 patients, portion it, and serve it on plates cannot b blamed if speed is the first consideration Though many patients may be unaffected by the conditions in whic they eat, there must be many others, especially among th voluntary admissions, who are upset by austerity crocker and slapdash service

The equipment and design of many ward kitchen needs bringing up to date, particularly by the provisio of water boilers for making hot drinks, double compart ment sinks, boiling-plates and grills, and, where food kept overnight, refrigerators The size of this proble is shown by a recent estimate that it would need £20,0 to bring the 42 ward kitchens in one large mental hospit up to standard Replanning these ward kitchens h been made more difficult by the fact that no two of the have identical dimensions

THE FOOD ITSELF

And what of the meals when they are finally served patients ? Below is a menu for a week in Novemb 1954, from a mental hospital in the Metropolitan ar with more than 2000 beds The hospital was built the 20th century, and it has a well-equipped kitchen a a progressive management committee , so it is n unreasonable to assume that the menu is at least up to average Nevertheless, the breakfasts and suppers obviously light The cost per head per week of feedi patients and staff was 15s , compared with 26s for gene hospitals in the same region

In most mental hospitals supper is finished by 6 P and for many of the patients it must be a long wait

	Breakfast	*Dinner*	*Tea*	*Suppe*
Sunday	Bacon Margarine Tea	Roast beef Cabbage Potatoes Stewed prunes Custard	Fruit cake Jam Margarine Tea	Cheese Pickles Cocoa
Monday	Eggs Margarine Tea	Boiled bacon Carrots Butter beans Bread pudding White sauce	Dessert apples Syrup Margarine Tea	Scotch
Tuesday	Porridge Marmalade Margarine Tea	Meat pie Cauliflower Potatoes Stewed fruit M. Blanc mange F Ice-cream	Jam Buns Margarine Tea	Savoury Pie Cocoa
Wednesday	Bacon Margarine Tea	Braised liver Cabbage Potatoes Currant roll Custard	Cake Syrup Margarine Tea	Brawn Mashed potatoes Cocoa
Thursday	Eggs Margarine Tea	M Fried fish Chips F Steamed fish Stewed apple Custard Lemon curd	Cheese Margarine Tea	Shepherd' pie
Friday	Smoked fish Margarine Tea	Roast beef Cabbage Potatoes Rice pudding Jam	Fruit Jam Margarine Tea (villas ice-cream)	Pea soup
Saturday	Porridge Marmalade Margarine Tea	Sausages Onions Potatoes Suet pudding Treacle	Fish paste Margarine Tea	Cheese and potato Cocoa

breakfast on a bowl of Scotch broth or a plate of pea soup The fact must, however, be faced that any attempt to give a more substantial or later supper will run up against the problem of staff Most mental hospital kitchens are worked on a single shift, concentrating on the midday meal, and with a minimum number of staff preparing breakfasts and suppers. Any improvement in ither of these meals or any postponement of the supper our must mean the employment of more cooks in preparation and more labour in distribution

In the past mental hospitals have relied on patients bour for much of the work in the kitchens, but lately is source of supply has been steadily contracting inly because of the growing numbers of voluntary tients. At the same time the difficulties of recruiting ined kitchen staff are even more acute in mental than other hospitals so even if larger kitchen establish nts were sanctioned it is very doubtful whether the itional places could be filled at the present rates of y and in existing working conditions.

The difference in the amounts spent per person per week food in mental and general hospitals is shown by the owing figures for 1953–54 in two of the Metropolitan ons

	Mental (including mental-deficiency)		*General*		*Difference*	
	s	d	s	d	s	d
on A	17	7	26	9	9	2
n B	15	9	24	9	9	0

ow the 9s is saved may be seen from the following ysis, based on figures obtained in recent surveys by Hospital Catering Advisory Service of the King's nd

Item	*Average weekly expenditure per head*				*Difference*		
	General		*Mental*				
	s	d	s	d	s	d	
	5	0	2	6	2	6	9s 3d
ry	3	6	2	6	1	0	
	1	1		1	1	0	
	1	3		9		6	
and vegetables	3	9	2	6	1	3	
rs	11	0	8	0	3	0	

se figures show a remarkable difference between standard of feeding in our mental and general pitals Admittedly there is a greater proportion of y old patients in mental hospitals, whose appetites smaller than the average On the other hand most the younger patients are ambulant and many are re compared with the great majority of general pital patients who are confined to bed

re money to buy provisions is however, only half t is required. If the other handicaps to a proper ndard of catering in our mental hospitals are to be come a far reaching programme of decentralisation re-equipment combined with an expansion and ding of catering staff will have to be undertaken r a detailed survey of all the mental hospitals could how much such a programme would cost; but ly the figure would run into millions and so long as present ceiling is imposed on the National Health ce budget these millions will not be forthcoming rtheless, the need for improvement is so pressing t it must be undertaken and when the need is great gh the means can always be found

---

WEST GERMAN HEALTH SERVICES

FROM A GERMAN CORRESPONDENT

A DRAFT law lately discussed by the West German lament regularises the relation of doctors to the al social insurance offices (*krankenkassen*) This law affects in the first place doctors already on the itaire offices panel—about 32 000 out of a total of st 0 000 in Western Germany Some 12 000 who not on the panel treat private patients only and since over 80% of the population are insured, the financial position of these doctors is precarious The draft law provides for an increase in the number of doctors on the insurance offices' panel from 1 in 600 to 1 in 500 patients The doctors remuneration will be based both on the amount of work they undertake and on the financial position of the insurance office in question Doctors and insurance offices are to set up arbitration committees with a jointly elected chairman, with powers to settle disputes

The draft law does not touch the problem of reform of social insurance most doctors regard such reform as necessary Nor does it promise decisive improvement in the difficult financial position of doctors already on the panel Under these circumstances opinion in the profession is divided A small minority think it best for doctors in time, to become Civil Servants The overwhelming majority wishes to preserve the profession s independence This opinion has been expressed by a group of doctors, led by Dr Schnitt of Munich who have devised a plan of social insurance reform

CELEBRATION AT HAMMERSMITH

May 13 1935 marked the start of a brave experiment on that day King George V opened the Postgraduate Medical School at Hammersmith L C C Hospital London There were other instances of links between teaching bodies and local authority hospitals, but none so close as this and heads were shaken wisely

In the event the association proved brilliantly successful The hospital which had been opened in 1905 as a poor law infirmary and workhouse had in 1930 passed to the control of the London County Council, and its practice was already of the standard set throughout the L C C service but the standard rose as it always does when teachers and taught assemble in wards. The school attracted a most able staff and the steady flow of students to it and of notable research from it attest to its continuing vigour

This week the hospital has been celebrating its jubilee and the school its twentieth anniversary On Monday these were visited by the Queen who was received by Mr Iain Macleod the Minister of Health

The Queen first visited the office of the Postgraduate Medical School, where she saw documents relating to the opening of the school by her grandfather in 1935 She then inspected the new metabolic unit which was opened this year and is equipped for all kinds of metabolic study particularly those relating to radiation hazards. She went to the Medical Research Council s radiotherapeutic research building opened in 1953 where she inspected the linear accelerator and pressed a button which set the whole cyclotron unit in operation for the first time She visited a gynaecological ward and a male surgical ward and proceeded to an exhibition illustrating research at the school

Among many elegantly displayed demonstrations from the department of surgery she saw an artificial heart-lung machine for maintaining artificial circulation during cardiac operations and descriptions of work on blood groups in relation to cancer and on transplantation of animal kidneys. The departments of medicine and biophysics displayed a mass spectrometer which has been designed for instantaneous simultaneous analysis of respiration gases—the only instrument of its kind in the country There was also a working model of the heart and circulation constructed for studies of the effect of valve lesions on cardiac output There were demonstrations of the investigation of thyroid function by radio-iodine and diagrams concerning work done on crush injuries during air raids advances in the treatment of malignant hypertension and investigations into the treatment of chronic bronchitis The Institute of Obstetrics and Gynaecology had demonstrations on placental localisation, studies of placental blood flow resuscitation of the newborn plasma-volume determinations, and vaginal cytology There was a large number of demonstrations from the department of pathology, including apparatus for measuring the total amount of radioactivity of a subject, which can be used for many purposes, such as the determination of the body content and exchange of sodium The department of hæmatology showed studies of hereditary anæmias, and the assay of vitamin B_{12} The department of bacteriology showed recent work on antibacterial drugs, vaccines, and bacterial genetics Lastly the experimental radiopathology research unit had a demonstration of autoradiographs and chromatography

Finally the Queen visited the nurses' home, where she signed the visitors' books of the hospital and the Postgraduate Medical School.

On Tuesday the hospital and the demonstrations were shown to distinguished visitors, and Wednesday was an Open Day

The Widdicombe File

XXV THE MERRYGOWHIMBLES

DEAR BREWER,

Lord Penballock has Sonne dysentery I use the present tense with hesitation, because I saw him and his shaggy pony (the one as weary and muddy as the other) returning from hunting today As a doctor I take this to be evidence of vigorous health, but as a bacteriologist I must believe the cultures on my bench · I do not think that his headmaster will welcome him until guaranteed free from infection , and so, at the risk of seeming fussy, we had better see three negative fæcal specimens before his return to Keate's Grove I doubt if the hardy splinter will object to the strict rules of quarantine

I know something of the origin of his infection because I was waylaid by his mother Her impudent curiosity would be an asset to any epidemiologist Beyond reasonable doubt the Honourable Anna has had the same complaint but has now returned to St Ethelberta's Her ladyship went so far as to allow that she herself had had a touch of the merrygowhimbles which she attributed to a Lithuanian recipe clipped from the newspaper Old Nanny admitted nothing—but nannies never do That, as you know, is all the household except for the daily, Mrs Gush Now my agents tell me that during the past fortnight the whole village has been troubled by a varying degree of looseness of the bowels Apples, beer, and the new baker share popular blame, but the one specimen of fæces which reached the laboratory grew *Shigella sonnei* I would have liked to confirm this by other specimens but know well enough that the calls of nature must be outrageous before we Widdicombians admit our frailty

Sonne dysentery has not had the attention which it deserves Without a pennyworth of evidence I suspect that it is a newcomer The bacillary dysentery which we heard of as students was an exotic disease limited in this country to the insane and those who lived in sordid squalor This mild but very infectious diarrhœa which lays whole regiments low in an afternoon and spares neither dukes nor dustmen was not in the curriculum It seems to have crept among us between the wars The first examples were a matter for excitement and much epidemiological activity Now we are resigned to the nuisance which it causes without knowing much more than we did It waxes and wanes for no clear cause It has been popular to attribute its prevalence to an increase in communal feeding so popular that what was an intelligent guess is now accepted as proven fact I doubt if this is all the story Soldiers, sailors, schoolboys, and convicts have eaten at a common board for years , were these stricken [illegible] dysentery when the free living world escaped ? It is too late to guess whence it came It seems pretty universal today and in warmer climates cannot be distinguished (except by the bacteriologist) from milder infections caused by other dysentery bacilli Neverthele I suspect that there is some essential difference Perhap *Shig sonnei* survives our inclement climate more easily or depends less upon flies for its transport, or the infectiou dose is smaller—or something else I wonder if it is disease which has yet to establish a steady symbiosis wit the English ?

I am expecting signals of distress from Miss Buxom St Ethelberta's Since the venerable Cobbleigh burst o laughing when she proposed to close the school beca three girls had threadworms, she turns to me for t advice which she seldom takes To her, as to many her kind, *mens sana* is less than nothing compared wi *corpus sanum* If, as I expect, Anna passes on h infection, the three Rs will give way to black draugh sulphur candles, and probably lysol baths When have said my piece on Sonne dysentery she will looking for another hygienic oracle

Most of what I know of this disease I learned du the war from a battalion of our own Royal Dartm Pioneers One morning about twenty men reported s with diarrhœa As soon as the doctor left the M.I roo twice that number sneaked in to beg a dose for t same complaint When I arrived two hours la there was still a sizable queue outside the latrin Clearly the daily sick return was not much use to epidemiologist

In those days I believed beyond doubt that an o break of any intestinal infection arose from a single sou via food or drink. (These North Devon men like B are not such boobies as we think) Since dysenter primarily a human disease, this source must be unsuspected carrier Since the explosive character of outbreak indicated a common article of diet and since water was chlorinated almost to the point of emitt green fumes, the carrier must be among the cook found him without trouble—all seven of them, of wh two had exuberant diarrhœa If any one of the se was the single *fons et origo* of the trouble I did not do not know how to distinguish him from his equ infectious fellows

The Pioneers taught me two other things Every during the preceding week one or two men had repor sick with diarrhœa This was no reason for alarm no fæces were examined, but I discovered that not of these had suffered on the fatal day In the week wh followed there were but two more infections and on these in a man who had been absent on that day E in the pride of my youth I did not attribute this mi to the hints on kitchen hygiene which I gav those pestiferous cooks Since then I have see good many epidemics of Sonne dysentery in closed co munities, and experience has on the whole confir the tentative guesses which I made in the camp Ballywillwill

I believe that for every adult sick enough to medical aid there will be two more with less se diarrhœa and perhaps four who excrete *Shig so* without evidence of infection They may do this for th days or three weeks some children seem to extend t period to three months The carrier of Sonne dysente (in the sense in which the word is used of an ente carrier) may or may not exist, but how he may distinguished from one who has suffered a recent ove hidden infection I do not know Such slight evidenc I have suggests that infection is introduced most o by such a convalescent Within the community infec spreads slowly at first, but how I do not know toilet-paper is flimsy stuff and *Bacterium coli* may found on the fingers of many of us it may be that the ordinary contacts of social life are enough to diffuse the infection *Shig sonnei* has been found in the dust under a sufferer's bed and an airborne spread is not inconceivable (I once looked at hundreds of throat-swabs with this in mind but without success) On a R.A.F station I watched the infection spread in a matter of weeks from dispersed site to dispersed site without any explosive demonstration of its presence

If symptomless infections are only half as common as suspect, the infection will be widespread before it is ticed The climax is reached when one or more of ose who cook or serve the food is infected The sick room *registers a dramatic—and deceptive—bound* The vice of the hygienist is sought, and, whatever it may it is an immediate success So too, I think, is passive unity There are no more infections because there no more susceptible subjects at risk How absolute how persistent is the immunity following infection do not know After I had had the disease I tried to ect myself for several months without result: I was bably fortunate or I would have been court martialled a self inflicted injury Not long ago I saw two demics within a twelvemonth in a home for little eciles whose habits made it certain that all the ates were exposed to infection In the first all the dren had diarrhœa except one newcomer who may introduced the infection In the second symptoms infection were limited to those children who had rived since the first epidemic Perhaps this was nce perhaps not

would not have you apply these surmises to all demics of Sonne dysentery without qualification rrhœa in an infant is an inescapable fact and I believe the proportion of symptomless infections among m is smaller When the disease is epidemic among the lation at large it is not easy to trace its spread It n the whole true that each family behaves as a closed munity—i e if one member shows symptoms most he others will be found to harbour the infection On of this the pattern *of the epidemic may be altered* by munal feeding and even in this tidy island, by rted water supplies Three hundred employees ted in one canteen catch the attention better than same number in a hundred separate homes

hat shall I tell Miss Buxom ? Experience has taught that the orthodox measures which we call hygiene are and disinfectant wasted Today or tomorrow it ht be possible to detect all those so far infected and re them. Apart from a distaste for the labour and s of examining a hundred and fifty fæcal specimens ne day I have not found this plan successful I ot detect *Shig sonnei* in less than eighteen hours knows whither it may have spread in this time ? les I am the first to admit that my methods may miss r two Since I know the nature of the infection I no point in culturing any fæces at all at this stage all not advise closing the school Apart from the se parents may reasonably object to a course h spreads the infection to brothers and sisters at Prophylactic doses of sulpha drugs have not ked in my hands nor I think in anyone else s I ld not care to dispense chloramphenicol widely and dly

shall advise Miss B to watch and pray—and to see no person with frank diarrhœa cooks or serves the d. My guess is that there will be the least interference h the normal working of the school if all the suscep es catch the disease as quickly as possible If I s logical I would omit the last part of my advice I know the difference between courage and hardiness

My part will come in four weeks time Then I shall wish to examine the fæces of the whole community at leisure and to smite those Shigellæ which linger

A hundred homes, and I do not know how many other academies will have reason to thank me if I succeed The girls have to produce a certificate of health when they return to school Parents have an equal right to such a guarantee

The telephone is ringing I wish Miss Buxom did not frighten me so

Yours sincerely

HARRY HAWKE

Medicine and the Law

Supervision in Children's Ward

A GIRL of 9, who was an inpatient in a children's ward was a walking patient and had her meals with other such children in a playroom It was a rule that they should remain seated until the end of the meal On Aug 13 1952 after the female orderly had left the children with their first course and gone to fetch the pudding the girl left the playroom, ran through the ward and suffered severe injuries when she pushed her arm through the lowest glass panel of a swing door in the ward The girl said that after the orderly left the room a boy had chased her with a dead mouse, and she ran out of the playroom into the ward and pushed open the first pair of swing doors She had looked round when about to open the second swing door and pushed her hand through the glass The boy's story was quite different he said that the girl in disobedience of the orderly had run out of the play room into the ward and swinging on the doors she had tripped over the stud used to fasten the doors back and put her hand through the glass.

In an action in the Queen's Bench Division for negligence against the hospital management committee Mr Justice Streatfield giving judgment on May 20, said that he was satisfied that these swing doors were normally kept open He did not think that the little girl was an untruthful child, but children were inclined to be imaginative especially if there were a stratum of truth in the story and there had been mice in the ward He was bound to conclude that the accident had not occurred because the girl was being chased with a mouse but because she had disobeyed the rules. Considering the duty of a hospital in supervising the children in the children s ward his Lordship said that he was not prepared to measure that duty by any more severe standard than that of a schoolmaster—namely that of an ordinary prudent parent Although he did not think that this was a case where the burden of proof was on the hospital to show that they were not negligent, he would in order to give the girl the benefit of the law consider the position as if the hospital did have that burden Lord Justice Denning in the case relating to an overturned inhaler had said that with all the skill and care that could reasonably be expected accidents and misadventures did occur

Mr Justice Streatfield thought that the hospital had provided adequate supervision in having the orderly to go to and fro and it was unthinkable that anyone should have to be there watching during her absences. If contrary to his view it was necessary for the hospital to discharge the burden of proof they had given an adequate explanation on which he would have held that they had sufficiently discharged it The action was dismissed

British Medical Association

THE association held its annual representative meeting in London from June 1 to 4, under the chairmanship of Dr I D GRANT (Glasgow) The annual meeting of the B M.A is in Toronto this year, from June 20 to 24

The chairman of council, Dr E A GREGG (London), in a summary of the association's activities, announced that a number of fresh claims had been made by the staff side of the Whitley Council for new salary scales for hospital medical officers It was regrettable that the new salary claim made on behalf of senior hospital medical officers had not found immediate acceptance In the public health field the most disappointing feature of the recent award of the Industrial Court was the apparent acceptance of the contention that the remuneration of public health medical officers should be related, not to that of other branches of the medical profession, but to that of other professional officers employed by local authorities

Dr Gregg also announced that the invitation sent to Russia last August had been accepted, and the B M A hoped shortly to entertain six distinguished Soviet doctors

The early business of the meeting included the election as vice-presidents of Dr A W S SICHEL, of South Africa, and Dr P T O'FARRELL, of Eire , and Dr ALEXANDER H HALL, of Hove, was named president-elect for 1956-57 This will be the first time since 1939-40 that a general practitioner has been president of the B.M.A

GENERAL PRACTICE

The meeting quickly got down to considering conditions of service and remuneration Dr A TALBOT ROGERS (Bromley), chairman of the General Medical Services Committee, said that the findings of the Willink Committee would have considerable repercussions on the future of general practice "We have been worried for some time at the rather unplanned way medical schools have been accepting students up to their full quota," he added Dr Rogers welcomed the precedent created over the inspection of doctors' surgeries, whereby the investigation was carried out by doctors , and he was able to announce that the Government had now agreed to raise the rate of payment to principals for trainee assistants by £75 a year

A series of motions asked for higher remuneration for general practitioners in view of the rising cost of living That from North Glamorgan and Brecknock, which called for an approach to the Minister, was selected for discussion In moving it, Dr A COLEMAN declared that the betterment factor should go up as the cost of living went up , he was dissatisfied with a variable central pool Dr H H GOODMAN (Newcastle upon Tyne) said that doctors could not, as in the past, pass on their increased costs to the "consumer" The working classes were always asking for higher wages and getting them In the North it was common for the young general practitioner to be receiving less than a miner This, too, was a question also of differentials There was a danger that what was happening on the Continent would happen in this country—the abolition of the middle classes Dr A V RUSSELL (Wolverhampton), however, pleaded "Do not let us approach this from the trade union angle" while Dr S WAND (Birmingham) pointed out that it was not Government policy to attach the higher income levels to the cost of living, and he warned that the time was not appropriate for negotiations motion was lost

Southampton division was concerned about ractice, because, Dr R M WARREN explained, they felt there was a risk of the State acquiring group practice premises as a step to a full time service Encouragement of group practices might result in a rota system, with harm to the doctor patient relationship Dr TALBOT ROGERS was reassuring, and Southampton's motion was lost

DRUGS FOR PRIVATE PATIENTS

On the subject of drugs for private patients, opposing views were heard from members of the Cohen Committee Dr F P BOOTH (Mid Cheshire) felt that drugs and appliances should be supplied under the National Health Service to private patients as a right and not as a concession Dr C W WALKER (Cambridge), a member of the Cohen Committee, drew cries of protest when he declared that this system would be liable to abuse, with debasement of State practice in order to induce more to become private patients Dr ENID HUGHES (Denbigh and Flint West) said that she was an aggressive member of the minority on the Cohen Committee who protested at this "violent injustice" The assertion in the committee's report that doctors in private practice would be unwilling to accept safeguards on prescribing was vigorously challenged Dr W WOOLLEY (Bristol) said that a questionary had been sent to 253 Bristol doctors Of the 240 who replied, the only 3 who were unwilling to accept such control were doctors who favoured a whole time salaried service , all 10 doctors who were wholly engaged in private practice agreed to such a condition Dr R HALE-WHITE (Marylebone) confirmed from his own observations that doctors in London were willing to accept control

Dr TALBOT ROGERS said that it was the wish and intention of the council to follow up the question of free drugs for private patients The meeting, on the suggestion of the Guildford division, passed resolutions regretting that no minority report in favour of the supply of drugs for private patients was issued by the Cohen Committee and calling on the council to find out how many priv practitioners concerned would be prepared to acce suitable safeguards

ECONOMY IN PRESCRIBING

Another lively subject was excessive prescribing a its penalties Dr FRANK GRAY (London) asked t meeting to reject a motion by East Kent which asked th an executive council should send a circular to gener practitioners when it became aware that a new prepar tion which was being prescribed did not appear to a drug forming part of the pharmaceutical servic no practitioner to be surcharged until this notice h been circulated Dr Gray said that this was asking a l body to tell the doctor, and the motion was lost

Dr G P HENRY (Glasgow) declared that not only th doctors but a good many of the more intelligent patie were concerned about the matter of penalties for exce prescribing The doctor was not entitled to prescri what he thought his patient needed He was entitle to prescribe only subject to what some committee other thought was an excessive drain on funds Th penalty in one case was £300 Why were men who we fined such large sums not given the option of impris ment ? Dr D F HUTCHINSON (London), howeve said that it was not a fine at all A doctor was entitle to prescribe any drug, the only caveat being that if h was called to account for his prescribing he had to justi it to the local medical committee—the elected repre sentatives of the practitioner and his colleagues alternative machinery had been suggested

Dr G D THOMPSON (Lancaster), who had heard cas a member of a committee, said that some were astound One doctor admitted that if a patient came in and for anything he got it. Another was prescribing at a rate £300 a month in excess of his colleagues—£4800 a year

OBSTETRIC BEDS

The meeting agreed that every general practitioner who desired it should have access to maternity beds Dr H N **Rose** (Stratford) who moved the motion, said that contact with hospital was necessary if the standard of domiciliary midwifery was to be kept up Dr L **Crawford** (St. Helens) and Dr R M S **McConaghey** (Torquay) described examples of successful arrangements of this kind

TRAINEE ASSISTANTS

The trainee assistant scheme came under its customary annual fire Dr H F **Hiscocks** (South East Essex) pointed to advertisements in the *British Medical Journal* "Required urgently, trainee assistant' But Dr J A. **Brown** (Birmingham) though he admitted that there had been failures, declared this was no reason to condemn the scheme as a whole The meeting thought the same and rejected a motion calling for the abolition of the scheme as ' unnecessary and extravagant.

ASSISTANTS IN GENERAL PRACTICE

Considering the report of the subcommittee on sistants in general practice the meeting agreed that assistant should enter into a written legal agreement hen accepting a post, either with or without a view partnership The subcommittee also recommended hat local executive councils should in consultation with cal medical committees, periodically review all cases in hich consent had been given to the employment of an sistant. Dr A V **Russell** (Wolverhampton) thought hat a legal agreement was all that was necessary but r **Ward** pointed out that the future of the profession as in the hands of these men—' their attitude to the ational Health Service and to a State salaried service his is very important) may be coloured by their perience in their first years as assistants The commendation was carried Another proposal was at a principal implementing a view should have the ght to claim retrospective payment on the basis of tional lists for a period up to a maximum of one ar; but this was less favourably received Dr **Joan** **appell** (North Middlesex) said that partnership like rriage should be entered into on the principle of tual regard not of financial gain The meeting ferred romance and rejected the recommendation

DISCIPLINARY MACHINERY

Dr B **Hirsh** (Manchester) declared that the doctor's putation should not be at the mercy of every Tom k, and Harry who lodged a complaint against him H **Guy Dain** (Birmingham) however, replied that disciplinary machinery in the National Health rvice was as much protective as administrative n improved variety' of the regulations was on the nt of being put into operation.

RECLASSIFICATION OF CLOSED AREAS

he South West Wales division was concerned about reclassification of closed areas. Dr M J **Evans** said South West Wales had been closed for four or five rs and there had been no change in the conditions recently it had been declared an intermediate area W F **Dornan** (Sheffield) chairman of the Medical actices Committee said that the power to declare an s closed was given by a reluctant Parliament and an more reluctant Representative Body to see that st use was made of general practitioner man power It was never given for the purpose of protecting the interests of established practitioners Many areas under-doctored in 1948 had had an increase of 20% in the numbers of principals and one area, near South West Wales had had an increase of 300%, so that the relative position of South West Wales had altered.

OBSTETRIC LIST

In the discussion of this recurrent theme Dr J C. **Arthur** (Gateshead) said that obstetrics and gynæcology was a major subject in the medical curriculum like medicine and surgery and a doctor should be as free to practise the former as he was the latter Dr L H **Booth** (Hastings) took the view that with the ordinary qualifying degree a practitioner was not experienced enough for the emergencies of midwifery The chairman, Dr **Grant** remarked that the present policy of the association was that any practitioner should be entitled without question, to have his name on the obstetric list and Dr J S M **Ord** (Glasgow) reminded the meeting that this was the position in Scotland

PAYMENT OF COMPENSATION

Dr J W **McCarthy** (Hendon) asked the Representative Body to reaffirm its earlier decision that compensation for practices should be paid forthwith Dr D L S **Johnston** (Halifax) declared that it was the doctors money and the Government was getting it at a cheap rate of interest. The motion was carried and the meeting also asked that the rate of interest should be raised to an adequate level, that doctors wishing to incur capital expenditure on new or improved surgery premises should be able to obtain an advance payment and that a practitioner taking another into partnership should also receive a payment

OCCUPATIONAL HEALTH

Approval was given to new rates of remuneration for industrial medical officers which Dr J A L **Vaughan Jones** chairman of the occupational health committee, described as a considerable increase over the former scale and bearing comparison with those in other grades He hoped that ultimately the Government would implement the Gowers report

MEDICAL ETHICS

Dr **Robert Forbes** (Hendon) chairman of the central ethical committee, believed there was some danger that the ethical standards of the profession might be lowered He divided doctors into three kinds those who were always above suspicion in their relationships with other practitioners because that came naturally to them those who wavered, and the black sheep who needed herding to keep them in the fold Ethics would avail us nothing, he added unless they were directed to the benefit of our patients.

The meeting carried a motion from South Essex urging that, wherever practicable exchange of medical details concerning patients should take place only between doctors and deploring the increasing tendency to exchange confidential medical details direct with lay persons Dr R D **Milford** moving this motion said that in the early days a general practitioner made arrangements direct with a consultant with the increasing use of clerical staff in hospital the position had altered considerably He also had misgivings in relation to insurance

In the matter of the utterances of doctors in the press and on radio and television, Dr C P **Wallace** (Guildford) suggested that it was unwise to accustom the public to receiving medical advice from anonymous sources and it was a serious infringement of the freedom of professional men "It is important that we have the opportunity of declaring our views on medical matters, subject to the ethical code" Dr F A Belam (Guildford) pointed out that articles in *Family Doctor* were signed The public were entitled to the best, and doctors specially qualified were recognised as experts Dr Forbes said that a special committee had been set up to go into this matter

PUBLIC-HEALTH SERVICES AWARD

Dr J B Tilley, chairman of the public-health committee, declared that the award of the Industrial Court, referred to by Dr Gregg in his opening remarks, was of the gravest concern to the whole profession and to the whole of the public-health service In this he was reinforced by Dr Dain, who asked how there could be a preventive service if its condition were so bad that doctors would not enter it Most schools had stopped running D P H courses The public-health doctors had been "left behind," to the great danger of the public The meeting unanimously endorsed a motion from Gateshead that, in view of the dangers caused by the low levels of remuneration in the salaried medical services of the State and local authorities, steps should be taken urgently by the association to bring the remuneration to a level comparable to that of the rest of the profession in hospital and general practice

DANGERS OF DIESEL OIL

Dr J O M Rees (Guildford) asked the council to draw the attention of transport authorities to the possible dangers of fumes from diesel engines It would, he said, be a pity if London Transport's plan to replace the largest trolley-bus fleet in the world by diesel engined vehicles went too far without the authority being warned that this might not be in the interests of the public Dr Belam said Dr H B Howell of Bristol had attributed the incidence of carcinoma of the lung in sailors in engine-rooms during the late war to diesel fumes, and he had found carcinogenic deposits on the windscreen of his car in Bristol, a city which had a diesel transport fleet Dr A B Kettle (East Somerset) felt that, in view of the large number of vested interests concerned, only a body like the B.M.A could be effective The resolution was carried

ARBITRATION MACHINERY

Dr Gregg warned representatives that the question of arbitration machinery was not as simple as some imagined There must be fair arbitration, in which the association could have faith He repeated the council's words "After careful consideration of the whole position, the council is of opinion that the profession would be well advised to rely, for the present, on ad-hoc arbitration arrangements when disputes occur" Dr J L McCallum (Westminster and Holborn) asked the council to examine the possibility of getting some form of arbitration for the profession alone, and to this the meeting agreed

CRASH HELMETS

There was sharp criticism of the Government's action in refusing to exclude crash helmets from purchase-tax Dr J M C Gill (Aberdeen and Kincardine) was sceptical of the effectiveness of propaganda, but his suggestion for compulsion did not meet with approval The meeting, however, agreed with Greenwich and Deptford, and urged that all forms of protective clothing, including crash helmets, should be free of purchase-tax

Mr A Lawrence Abel (Marylebone) told of the delegation which went to the Board of Customs and [illegible] January The delegation pointed out that each [illegible] young men and women died on the roads of Britain and 18,000 were seriously injured, and a large number of these deaths and injuries would have been avoided if crash helmets had been compulsory The Customs and Excise officials told the delegation that no words of English could be conceived which could include crash helmets in the exemption from purchase tax of protective helmets worn by miners and quarrymen. "So we offered to send them a junior 16 year old clerk," Mr Abel added, as he opened fire on the authorities The tax people were getting 10*s* to 15*s* on each helmet, it was impossible to assess the value of the young lives lost, but the cost of the injuries was £4½ million—enough to run a hospital service in any one region There had been six months' delay since the delegation's visit, and nothing had been done, while hundreds of people had died on the roads If there was no improvement when purchase-tax was taken off, then let there be compulsion for wearing crash helmets

CONSULTANTS AND SPECIALISTS

Mr J R Nicholson Lailey deputised for Dr Rowland Hill, chairman of the Central Consultants and Specialists Committee, who was prevented by illness from attending the meeting Mr Nicholson Lailey admitted that the administration of the Joint Consultants and Specialists Committee might seem tedious, but warned that it would be a mistake to force a divorce between the Central Consultants and Specialists Committee of the B M A and the Colleges Nothing should be done which would enable the Government to negotiate separately or cause the consultants and specialists to set up their own organisation

Dr R P Liston (Tunbridge Wells) did not want the B M A to come to the hopeless position of the T U C in dealing with autonomous bodies, and Dr J A Pridham (Dorset) said that when the colleges cam down from their academic groves to the dusty are they had not the same experience as the B.M.A It w agreed that the council should review the relationsh of the Central Consultants and Specialists Committee the joint committee The council was also instructed consider the desirability of withdrawing from committe B of the Whitley Medical Council, "in view of the fa that this negotiating machinery is not work satisfactorily"

THE BAN ON HEROIN

Many speakers thought poorly of the ban on hero both for its effect and the way it was, imposed Dr J W Taylor (Aberdeen and Kincardine) declared "We are being denied the use of a most valuable dr for which there is no substitute We feel there was enough consultation with the general practitioners w are the greatest users of heroin" Dr Gregg said th the picture of heroin addiction presented to the standi medical advisory committee of the Central Health Servi Council was so dreadful that the sacrifice Britain wo make in not using heroin seemed small in compariso but he emphasised that he was not a member of th committee as a representative of the B M A It was mo regrettable that the B M A was not consulted and had no opportunity of circularising divisions to fo their opinion

Dr J S Happel (Winchester) asked "What of the other drugs of addiction? Where will the guillotine fal next?" Dr R Hale White (Marylebone) noted th in spite of the ban in other countries addiction there w increasing Dr John Noble (Blyth, Morpeth) remarke that the Government was giving pethidine to midwi and morphine to miners—and withholding heroin fro doctors Dr G E Moloney (Oxford) wanted to kno whether, because there were whisky addicts, whi manufacture was to be banned? (Cries of "No

And should the export of whisky be prohibited? ("Yes.")

Dr A. I MACLEOD (Outer Isles) however appealed to the profession to do without heroin in the interests of the world and Dr J G M HAMILTON (Edinburgh) said "We must regard ourselves as a responsible body—responsible not only to our patients and ourselves, but responsible internationally" Dr WAND deprecating parochial remarks, said the question was whether a few sufferers should be allowed a little extra suffering to try to solve a grave international problem

The meeting passed a resolution protesting against and asking for a reversal of the ban on the manufacture and use (but not the export) of heroin The resolution also pointed out that in the absence of consultation with the B.M.A. the Government could not claim to have consulted the medical profession

HOSPITAL MEDICAL STAFF

Mr NICHOLSON LAILEY announced that a claim had been made to restore the relative financial position of S.H.M.O.s. Dr E W, GOODWIN (Leicestershire and Rutland) said that consultants were overworked and registrars and S.H.M.O.s were doing the work of consultants. This could be overcome by increasing the consultant staff, which would also give incentive to hospital work. Introducing a motion from Dorset Dr PRIDHAM declared that house-officers were living near the poverty line Dr ANNIS GILLIE (Paddington) spoke for married women doctors, saying that they would like regular part-time hospital work which should not be of a "dead-end" type

HOSPITAL ADMINISTRATION

Criticising the Bradbeer report on the internal administration of hospitals, Dr V COTTON CORNWALL (Liverpool) saw in it interference from the lay secretary Dr L A GIBBONS (Reigate) said doctors were to be made the scapegoat of anything which went wrong in the hospital. Thousands of pounds were spent to convert a mansion into offices for little empire builders, while doctors were told to economise in dressings Dr A. KENE (Liverpool), referring to the Bradbeer recommendation for equal tripartite administration—medical, nursing, and lay—observed "The three members are equal partners, but the group secretary is twice as equal."

The meeting agreed with Liverpool that everything concerning the patient must be of importance to the clinician in charge and that therefore, lay and ancillary services must be subordinate to the medical so that equal tripartite administration was not in the interest of the patient Under no circumstances should the medical and nursing personnel be under the control of lay administrators.

STUDY LEAVE

Dr D S GREIG (Stirling) asked the Ministry and the Department of Health for Scotland to reinforce their instructions to regional hospital boards to make study leave available to hospital officers. Boards should be stimulated to provide locums where necessary one Ayrshire registrar had been waiting two years for study leave simply because he could not be spared

POLICY REAFFIRMED

On the last day of the meeting the Representative Body reaffirmed its policy on two points: by again expressing its strong opposition to a full time State salaried service and by stating that the Spens reports should still remain the basis in all negotiations on remuneration of doctors in every branch of the National Health Service

PREREGISTRATION POSTS

Dr ALICE GILBY (Westminster and Holborn) said that doctors in their preregistration year were getting a new 'slant' on the aphorism of Hippocrates "Art is long, Time is short, Judgment difficult, Opportunities fleeting" They complained that there were not enough preregistration posts in the larger hospitals they did not want to go away to the smaller ones for that prejudiced their chances later As it was difficult to dovetail posts, they might be faced with at least several weeks unemployment. Whitley committee B had not been able to find a means of giving them reasonable holidays The meeting asked the council to examine the situation and in view of the urgency to take immediate action in the light of their findings. Mr D S PRACY (Nuneaton and Tamworth) said that at present many listed preregistration posts were not suitable because there was insufficient supervision of the preregistration houseman by senior residents

POLITICS AND THE HEALTH SERVICE

The meeting declared that it was undesirable and detrimental to the interests of the health of the nation for the health service to be a means of gaining political capital, and that the service should be removed from the political arena. The motion was supported in two speeches which were not quite without political bias Dr J B W ROWE (Harrow) pointed out that at the last election one party had promised to abolish all charges and make a so-called free service whilst the other had said it would build more hospitals. It would be better to establish the service on a sound economic basis and administer it on non political lines. The present political interest, he thought was bad for mental health tending to make people introspective and neurotic Dr B HIRSH (Manchester) spoke of the 'fanfare of nauseating ballyhoo with which the service was introduced

TREASURER'S BADGE

Mr A M A MOORE, who retired as treasurer of the B.M.A. in 1954, presented a Treasurer's Badge to the association and invested his successor, Mr L DOUGAL CALLANDER.

Public Health

Salaries in the Public-health Service

COMMITTEE C of the Medical Whitley Council has accepted the Industrial Court's award on salaries of doctors in the public-health service[1] and has recommended all local authorities to put this into effect as from Jan 1 1955 The committee has issued a circular[2] containing detailed recommendations on salaries from that date.

Tuberculosis in Eire

The report[3] of the Department of Health for Eire for 1953–54 includes figures emphasising the remarkable change in the tuberculosis situation in Eire in the past few years The number of patients receiving treatment has steadily increased while the number of new cases coming under notice has decreased. The death rate has fallen steeply

Year	*No. of patients treated*	*No. of new cases under notice*	*Deaths*	*Death-rate per 100,000 population*
1949	25 050	7339	2717	91
1950	27 959	6706	2380	80
1951	30 338	6055	2162	73
1952	33 839	6705	1579	51
1953	36,03	6669	1190	40

In England Now

A Running Commentary by Peripatetic Correspondents

WITH the railway strike the steel and coal may not be getting through, but the workers are And in London that is astonishing Leaving my home a dozen miles to the South I enter a line of traffic pelting along until half a mile short of the first roundabout There we stop, start, and stop again yard by yard until the roundabout is passed Then off we go to the next junction. Motorists have summoned hitherto unfathomed resources of patience never a hoot, and seldom a cut-in So have the non-motorists who wait good-naturedly at the bus-stops, or between the bus-stops hoping for a lift They start early and they may get there a bit late, but get there they do, and, remembering the frequent and crowded commuters' trains to the South that seems almost incredible. But if the general public has acquitted itself well, the police have done even better Working twelve-hour shifts, they have befriended us at every turn Parking the other day on the Embankment outside Scotland Yard I was approached by a constable Would I, he asked, mind going a bit further down? I went further down and saw him approaching almost at a run Trouble, I thought But no, he had come to ease me into a berth And so it has been all along

About the causes of our discomfort the people who have come in my car have been reserved Most of them have been more concerned about our stuttering economy than about their own uneasy journeys

* * *

A rail strike in full swing and a State of Emergency proclaimed Guy's simply had to be in on this!

We had bought a 1939 25-seater coach to convert to a caravan for our Continental holiday this summer Last week, with great effort, we removed the seats This week, with greater effort, we replaced them We obtained the permission of the Ministry of Transport to use this vehicle of unparalleled reliability and luxury, and dawn next morning saw us off Pulling up at our first stop, my conductor shouted his war-cry, "Purley, Croydon, Elephant, and London Bridge" Silence ensued among the surprised crowd, then the small voice of a schoolboy cried "Straight on, guv'nor, straight on!"

After this shattering start, we soon had a busful of passengers, who regarded us with obvious misgivings but settled in their seats or allotted standing-room with commendable resignation Extracting our fares, we were surprised to learn that other pirates had been on the road before us and were charging even more Imagine our fury at undercutting our allies and patriotic colleagues!

Streatham Hill, a full load of 6 tons, and a warm day spelt disaster to the old bus She coughed, choked, and stopped We lifted the bonnet and applied a universal remedy with this bus—blowing down the petrol feed with a bicycle pump Rewarded by the petrol cap flying off the tank, we replaced the bits and climbed in Surprisingly, the engine started, and again we staggered along

We soon learned the language of our adopted calling as, asphyxiated by carbon monoxide and boiled by the heat of the engine, we threaded our way through the packed traffic The final right turn into London Bridge Approach, with Austin 7s under the bonnet and cyclists under each mudguard, was as exciting and dangerous a piece of busmanship as any After nearly two hours of their unwilling company, we dropped our passengers To our astonishment, some seemed genuinely grateful and one or two even asked what time we were running that evening

One disappointing feature about our first week as rivals to the London Transport Executive was that we made just 7s profit But maybe, by the Executive's standards, that's good going!

* * *

"Harley Street Doctor," who contributes to one of the evening papers, has been advising his readers on how they [illegible] "perfect patients"—from his point of view [illegible] be objective, honest and accurate in describing [illegible]oms" Yet they "should avoid volubility"

"It will be helpful if the patient has a good *general* idea of how the body works" But "few people are more difficult to handle than those who think they know *more than the* doctor in both diagnosis and treatment"

In response to the question how long has a symptom been present, the doctor "will not be satisfied with the reply 'a long time' He will want to know how many days weeks, months." (Does he really expect such information? I have more than once encountered patients who have completely forgotten an extensive laparotomy until their attention was directed to a long abdominal scar) And also "if the symptoms are getting better or worse, are continuous or intermittent And what relieves or aggravates them?"

"In mentioning previous illnesses, don't ignore any because they appear to be too trivial"

No, dear "Harley Street" colleague, it is not the patient's obligation to distinguish irrelevancies from essentials, trivialities from matters of importance Nor can one expect it He is likely to be scrupulously accurate about the weight of the case of bananas that fell on his foot, and to consider as of the greatest importance the number of the motor-car that knocked him down (which indeed it well may be to him, with his eye upon compensation, or to the police with the prospect of legal proceedings) I once had a frantic telephone message at 3 A.M from a highly educated man, unable to sleep through the pricking of conscience, recalling that during our consultation he had informed me that he was 56 years old whereas he would not reach that age until the end of the following week For all he knew, such a detail might be of profound significance in my understanding and treatment of his complaint

As an elder (perhaps not better) soldier, I feel disposed to suggest to the writer that the core of the matter is not the education of his prospective patients but the *continuous* education of himself To obtain the necessary coöperation is the doctor's business the adjustment to get en rapport naturally varies with the individual, and the really good doctor converts every patient into a "perfect patient" That surely is the art of medicine.

* * *

My quince is in full bloom, if ever a quince is in full bloom It always reminds me of chickenpox, for it flowers seem to come out in a series of crops When I went away on Wednesday, May 25, there were a few buds, and when I returned on the Saturday these were in full flower, of the colour of typhoid spots, which resemble the tint best illustrated by the English unofficial rose Besides the flowers already out, there are now many more buds, which I expect will burst forth on Sunday, Monday, and Tuesday, for some are tight and others loose It is unwise to count one's quinces be they have matured, but my two trees have in the often produced a marketable surplus I wonder whe the quince in Crete, which the O E D suggests is natural habitat, has sweeter fruit than our own

* * *

At last I have been to a Roses match at Old Traff With plenty of cricketing characters on both si there was little danger of boredom, and what be than the moment when Statham was called upon prevent—and only just, by jove—a hat-trick by Yorkshire rival, Trueman As the match fluctua excitingly, the steady stream of evening newspapers w one move behind "Lancs steady start" we read con ingly as the middle batsmen failed, but, safe in knowledge that the tail was wagging before our v eyes, the headline "Lancs slump" did not worr It was only when we came to read our pink or gre sports specials on the way home that we realised full glory of the day's proceedings, not only had important Yorkshire wickets fallen in the last minutes of play, but first-class cricket had been rain off nearly everywhere except Old Trafford Now th really is something to make a Mancunian holiday!

* * *

Overheard in outpatients

"What is your job?"

"*I work a Hollerith machine for the* C W.S"

"And what do the C W S use a Hollerith machine for?"

"For punching holes in cards"

Letters to the Editor

CIVIL SERVICE MEDICAL APPOINTMENTS

SIR,—The secretary of the Civil Service Commission is surely all too ingenuous in his reply last week to "Toad Beneath the Harrow" What he has done is to seize on a few words in the Toad's letter and avoid replying to the main point of it.

The point is that in the document issued by the Civil Service to applicants for appointment as medical officers on p 10 under the heading of prospects, it says that higher posts in the medical officer class are normally filled by promotion from the grade of medical officer and then goes on to refer to 14 posts above the grade of principal medical officer This, as the secretary of the commission must know is not a statement of fact. As the Institution of Professional Civil Servants pointed out in the evidence that it submitted recently to the Royal Commission on the Civil Service

> "One of the standing grievances of the medical officer class is that to an extent unknown in any other Civil Service class higher posts are filled by direct recruitment instead of by promotion. It is a fact that in the appointments since the end of the war not one of the chiefs other than the principal medical officer acting as chief in the Ministry of Fuel and Power has served as a basic grade medical officer in the Civil Service These chiefs and some of the deputies and indeed some of the principal medical officers, have been drawn from outside the Civil Service It is a serious reflection on the administration of the medical Civil Service that there is this constant bringing in of officers from outside for it causes intense dissatisfaction and frustration among the highly competent staff with many years of efficient service to their credit"

There is also an interesting comparison to be made between the administrative class in the Civil Service and the medical officer class. In the medical Civil Service out of a total of some 506 officers, temporary and established, there are only 135 above the level of the basic grade: that is to say on the face of it, a one in four chance of promotion For the 703 assistant secretaries in the administrative class in the Civil Service, there are no fewer than 310 higher posts that is to say a one in two chance The practice is, however vastly different In the medical officer class the position is as described in the previous paragraph

In the administrative class it is most exceptional for any post in the higher levels to be filled other than by promotion

While these facts remain as they are the Civil Service Commission ought to be more careful in its statements to prospective recruits to the Civil Service, unless it wishes to be accused of dishonesty

QUARANTINE MEASURES IN POLIOMYELITIS

SIR,—The article by Dr Goffe and Miss Parfitt in your issue of June 4 will arouse widespread comment and is of the greatest interest

There are of course two schools of thought on the spread of poliomyelitis. There is the "narrow stream" concept of Dr W H Bradley of the Ministry of Health and there is the concept propounded by Dr F O MacCallum director of the Virus Reference Laboratory Colindale The latter concept is based on studies of the presence of the virus in sewage and favours a broad stream—the "epidemic" property of the virus concerned determining whether an epidemic shall occur

Most medical officers of health acting on the former view make the recommendations favoured by the W H O expert committee and used apparently without success in the epidemic investigated by Goffe and Parfitt The fact that a few contacts may excrete the virus in the stools for longer than 21 days will not invalidate this period for me until investigations on a much larger scale are carried out Dr Bradley in his paper at Scarborough in 1953 drew comparisons with scarlet fever and diphtheria and said "Epidemiologists have long since learnt that although corynebacteria and streptococci are extremely widespread in nature strains capable of hurting man spread locally giving rise to discrete outbreaks" So in this respect, both the epidemiology of the Ministry and the virology of Colindale are in agreement.

Personally I believe the only answer is in widespread immunisation which has assisted the natural disappearance of diseases such as diphtheria and yellow fever in human beings, and distemper and hard pad in dogs. Until this day arrives, isolation of cases and quarantine of contacts must be the measures to be followed.

But splendid investigations such as the ones you have published are in line with the W H O recommendation for further study of the practicability and effectiveness of isolation and quarantine as applied to first families in a community in the control of poliomyelitis.

Public Health Department,
Beckenham, Kent

L R. L EDWARDS
Medical Officer of Health.

TREATMENT OF CHRONIC AMŒBIC DYSENTERY

SIR,—In your issue of March 26 Dr Andrade reproves Lieut Colonel Inder Singh for stating that emetine will control acute amœbic dysentery, but that the *amœbic cysts are not affected* Dr Andrade suggests that it is irrational to suppose that the finding of harmless cysts provides any information other than that they must have originated from trophozoites He implies with obvious reason that an egg must have been laid by a pre-existing hen and that the only rational treatment is to attack the hen not the egg But he goes further and states that the presence of cysts is merely indicative of an infection of the bowel *wall* with amœbæ. There is a good deal of evidence that this is not so and that the presence of cysts indicates rather strongly that the pre existent trophozoites are living in the *lumen* of the bowel.

This theory has been reintroduced by Hoare and has much to recommend it in explaining the relationship of infestation to morbidity in amœbiasis This theory of intraluminal symbiosis carries also a lesson in therapeutics.

It is well known that

(1) Patients with the dysenteric form of amœbiasis pass trophozoites not cysts.

(2) In asymptomatic and mildly symptomatic amœbiasis cysts are very often passed and trophozoites are often not seen

Recently we have shown that certain drugs can convert the trophozoite passing patient into the asymptomatic cyst passer and these findings will be published shortly

> *We believe that these observations support Hoare s* contention that amœbæ can live free in the bowel and that when they do so they achieve the ultimate design of their existence and reproduce themselves by cyst formation as Nature intended Their intraluminal habitat does not necessarily imply that they live *only* in the middle of the bowel contents. If they did it might be presumed that only a dose of Epsom salts would be needed for complete eradication It may be reasonably contended that they live in the contents of the crypts but essentially they do not invade the tissues We believe therefore that the passage of trophozoites is evidence of invasion, of ulceration and of true pathogenicity: and that the passage of cysts is evidence of lack of invasion and ulceration and in favour of the amœbæ living harmlessly as commensals in the lumen of the bowel

If this is true, Colonel Inder Singh s *observation* (and indeed that of many other observers) that emetine does not eradicate cysts is easily explained For a systemic amœbicide acting on the tissues by virtue of its being carried by the blood, would not be expected to destroy either cysts or their antecedent amœbæ in the lumen of the bowel

We feel that when patients are found to be passing cysts they *must* be treated with intraluminal amœbicides —e g , the antibiotics and diodoquin For extra security it is sensible to add a harmless systemic amœbicide such as chloroquine In dysenteric amœbiasis the systemic amœbicides, emetine or chloroquine, are mandatory as well as the intraluminal amœbicides

We believe the finding of cysts indicates the presence of the intraluminal phase, but the finding of trophozoites, apart from possible hæmatophagy, does not distinguish between the two possible phases Thus, the differential finding of cysts or of trophozoites has a considerable significance in treatment and prognosis We consider that much of the controversy over the results of the many modern treatments reported in the last few years, is due to failure to appreciate the differences between the intraluminal and invasive phases of amœbiasis

Amœbiasis Research Unit,
South African Council for
Scientific and Industrial
Research, Durban

T G ARMSTRONG
A J WILMOT
R ELSDON-DEW

SIR,—Lieut -Colonel Inder Singh displays another common misconception, in his letter of May 28, when he says that " unless both cysts and amœbæ are destroyed, some of the cysts may develop into amœbæ before they are excreted and thus restart the infection "

In kittens, acute *infection* can be readily produced by rectal injection of material containing cysts of *Entamœba histolytica*, but in man the cysts do not undergo any further development in the intestine and, once formed in the lumen of the bowel, do not excyst again in the same host The cysts, therefore, are not parasitic and are harmless to the host in whose bowel they are formed They are, of course, infective when swallowed by a new host

It is customary to use a combination of drugs in the treatment of amœbiasis not because it is necessary to kill amœbæ *and cysts*, as is suggested by Colonel Inder Singh, but because amœbæ live on the mucosal surface of the large bowel and within its lumen and also penetrate into the mucosa and submucosa, thus necessitating the combined use of an amœbicide which acts locally in the gut and one which exerts its action after absorption

I repeat that cyst destruction forms no part of the aim of treatment and, in support, may I quote Dr A R D Adams,[1] of the Liverpool School of Tropical Medicine

> " It follows therefore that any treatment given to eradicate the infection of the large bowel must be *directed against the* amœbæ there, and it is quite pointless to consider treatment to destroy the harmless inert cysts which form in the stools, their presence there being merely indicative of the presence of an infection with amœbæ This matter is one of importance and is worthy of stress in view of some statements in the literature in relation to the drug treatment of intestinal amœbiasis These statements assert that one drug is given to *destroy the amœbæ* and another to destroy the cysts, it having been observed that the drug destroys the latter in vitro It is by no means certain that any drug given by mouth destroys cysts *within the lumen of the gut* , it is much more probable that the parent amœbæ would be destroyed by such a drug, and that it is their destruction which accounts for the disappearance of the cysts from the stools No treatment at all is necessary to destroy the cysts , and indeed, if it were possible purposively to do so their destruction would have no influence on the parent infection When the treatment is stopped, further cysts would immediately reappear in the stools so long as the parent infection remained "

Calcutta.

C B ANDRADE

CANCER

SIR,—I write to disagree with Dr Hazel Baker (May 21), for I fear that she is arguing from the particular to the general

Because one surgeon surprisingly insisted on having an exploratory laparotomy for (as he was assured) non-existent carcinoma, there is no reason why the public should not be made aware of two important facts. These are (1) the varied symptoms of cancer , and (2) that if these symptoms are reported without delay to their doctor there is every chance of a cure, and not necessarily by the knife

Many will admit that there is nothing more alarming than poliomyelitis, and yet look at the enormous amount of publicity its symptoms have received in the press and through the B B C —and most valuable publicity in *my view insomuch that* parents and others now are amply warned

I would like to see equal publicity given to cancer symptoms There will always be the nervous person too frightened to do anything about it, but there may be hundreds of others—luckily more courageous—who would take advantage of this knowledge and *promptly* enlist medical advice to prove or disprove their suspicions.

I write not as a member of the medical profession—though married to one—but as one who lost a very near and dear relative who died of cancer because he was too late in asking for medical advice—not through fear but through ignorance

Woodhall Spa,
Lincs

LILY BOYS

RENAL SHUNT IN SHOCK

SIR,—A large number of experimental studies on the renal circulation in shock have been undertaken, but comparatively few observations on human beings have so *far* been published The *following observations* may therefore be of interest

A patient, aged 28, with aortic coarctation and hypertension, was subjected to renal-vein catheterisation At 13 hr 30 min hyposulphite and *p* aminohippurate (P A H) clearances were started, causing *some vomiting* They gave the following results

C_{Hypo}	C_{PAH}	Blood flow	Filtration fraction	E_{PAH}	Blood pressure (arm)
140	469	610	0 18	100 %	180/100

At 16 hr 20 min , under radiographic control, *the catheter* was seen in place in the renal vein and the venous pressure was 6 5 mm Hg Maximum P A H extraction was obtained Oxygen and bicarbonate levels in the renal venous blood were within the normal range

At 16 hr 30 min the patient showed all the clinical signs of shock and the blood-pressure of the upper limbs fell to 120/60 At this moment blood from the femoral *artery and renal vein was obtained* and the amount of O_2, CO_2H, Na, and K was estimated The following were the figures obtained

—	Oxygen		CO_2H		Na		K		Venous pressure
	Artery	Vein	Artery	Vein	Artery	Vein	Artery	Vein	
Before shock	?	10 06	?	40 50	?	?	?	?	6 5 mm. Hg
During shock	11	11 44	47 04	47 64	130	139	3 7	4 3	0

About 5 minutes afterwards all the signs of shock increased and no more blood was obtainable by aspiration through the catheter *As radiography* confirmed that the catheter was well placed in the renal vein, it was evident that no blood was circulating through the kidney at this stage Saline *solution injected* by the catheter was reaspirated without blood Thus the renal circulation had completely ceased Shortly after the removal of the catheter the patient recovered from shock.

---

[1] *Practitioner*, 1952 168, 419

We have no knowledge of the oxygen content of the arterial blood of this patient before shock but we have no reason to assume it was not normal The oxygen of the venous blood both in the right auricle (8 51) and in the renal vein was normal The sudden and sharp ue of the venous oxygen and bicarbonates during hock can be explained only by a striking readjustment of the renal circulation during shock The following ratio serves to explain the exclusion of the functional renal tissue in shock when the circulation through the kidney is maintained

$$\frac{\text{Renal arteriovenous difference in } CO_2 \times \text{ blood flow}}{\text{Renal arteriovenous difference in } O_2 \times \text{ blood flow}}$$

No other explanation seems possible than the presence in the human kidney under conditions of shock, of a shunt such as that described by Trueta and his associates —an arrangement whose existence in man has been doubted.

The complete suppression of the blood flow through the renal vein at the more severe stages of shock seems to accord with Van Slyke's concept of the sacrifice of the renal circulation We are not in a position to explain the levels of extraction of Na and K but we must remark that the latter appeared in a slightly higher concentration in the blood of the renal vein as if K had been liberated by the anoxic tubular cells

In this case we were not able to detect spurting of the renal venous blood, but in another patient under shock spurting was noted In this case the arteriovenous oxygen difference was normal.

A BARBITURATE ANTAGONIST

SIR,—When one of us (F H S) replied to Dr McElligott (April 16) the excellent article of Dr Wright [1] was not available for perusal. However the statement (May 7) that little barbiturate would remain in the body after six days was not a generality but was based on the experience of one of us (N E W McC) who has been studying barbiturate metabolism for some years past

Dr Wright has found that phenobarbitone disappears from the plasma at the rate of 15% per day and calculates that after the ingestion of 72 grains of the compound, there would be 27 grains present at the end of six days. This calculation appears to imply that phenobarbitone is removed from the body solely by renal excretion whereas it has been established that some % of administered phenobarbitone cannot be recovered from the urine

In one of our patients who was known to have ingested at least 100 grains of phenobarbitone traces of compounds showing a *spectrophotometric absorption similar* to barbiturate absorption were present in serum and urine eight days later We have however spectrophotometric and other evidence which strongly suggests that phenobarbitone was not the only compound which is contributing to the absorption This evidence was supported in experiments with dogs

As we have said it has been established that only some % of ingested phenobarbitone is excreted as such in the urine [2] The larger proportion is metabolised in some unknown fashion but from what we know of the destruction of other barbiturates it is likely that the ring structure remains intact at first We also have evidence that at least one of the possible decomposition products of phenobarbitone has an absorption similar to that of the parent substance In view of the fact of such destruction *of phenobarbitone in the body I would suggest that* some of the material estimated spectrophotometrically by Dr Wright [1] is of metabolic origin In other words in the absence of detailed knowledge of phenobarbitone metabolism the results of analyses obtained by spectrophotometric methods should be interpreted with caution

Also we do not agree that the worth of new barbiturate antagonists can be evaluated by a measurement of drug levels in the blood The only test is the pragmatic one of a lessening of the duration of coma and the mortality rate. The suggestion that barbiturate intoxication is best treated by conservative methods will be the subject of another paper

ELECTRIC BLANKETS

SIR,—The attention of the Standing Interdepartmental Committee on Accidents in the Home of which I am Chairman has been drawn to the letter by Dr Maddison in your issue of April 16 giving directions for making an electric blanket The committee think it desirable that your readers should be warned that blankets of this kind may be dangerous unless certain precautions are taken which Dr Maddison would no doubt have wished to mention had space permitted These include the incorporation of thermostats and secondary fuses as a protection against overheating and the use of a transformer embodying a safeguard against a fault developing between the primary and secondary windings which would otherwise have the effect of making the blanket live at mains voltage

In addition it should be borne in mind that the repeated folding of conductors of the type suggested would in time cause deterioration of the insulation and breaking of the conductors themselves giving rise to risk of burns and shock

Since considerable technical experience is necessary to make the above precautions effective it may be unwise for anyone without proper qualifications to attempt the construction of an article which requires highly specialised knowledge for its successful production

Home Office,
London S.W 1

AUSTIN STRUTT

DIURESIS FROM CARBONIC ANHYDRASE INHIBITION

SIR,—Your leader of April 2 was remarkable in its scope and balance and certainly represents the best available statement in this complex and controversial field. May I be permitted a few comments on several of the technical questions raised ?

(1) The maximal *rate* of HCO_3^- excretion following acetazoleamide ("Diamox") may show a logarithmic relation to dose but this is only in the range 0·1 mg per kg to 5 0 mg per kg [3,4] Above this range and at clinical levels the dose-response curve is flat; *there is little difference between HCO_3^- excretion rates* following 5 or 100 mg per kg orally [4] This suggests that inhibition of renal carbonic anhydrase is essentially complete at the therapeutic dose range of 5–10 mg per kg The *total* amount of bicarbonate excreted after a single dose however is a function of dose in the 5–100 mg per kg range since the dose determines the duration and hence the final magnitude of effect

(2) The diuretic effect of acetazoleamide is *not* necessarily dependent on plasma HCO_3^- concentration in the range 12–22 m eq per litre Lowering of *plasma* HCO_3^- by hyperventilation or by a moderate single dose of acetazoleamide itself does not block the renal response since in these situations

comparatively little "buffer base" is lost, it appears that it is the *total* quantity of base lost or net body acidosis that prevents the renal effect Such acidosis is achieved on continued administration of drug but is imperfectly reflected, in quantitative terms, by plasma HCO_3^- concentration [4]

(3) There is no doubt that opinions on the diuretic effectiveness of this drug "vary from virtual nihilism to considerable enthusiasm" But in the nihilistic paper [3] no patients were treated for more than one day, and in the enthusiastic papers there were no controls in whom diuretic therapy was withheld [5,6] Certainly it should be possible to chart a course between these extremes You foster one notion that has led some to nihilism—the idea that there must be chloride loss to relieve œdema But until the careful documentation that you call for has been made, it will be well to reserve judgment on this point

(4) Excretion of potassium in cardiac patients otherwise resistant to acetazoleamide has not generally been large On the first day of drug the K^+ output does not appear to exceed greatly the daily intake,[3] and output diminishes strikingly on the second and third day (as it does in the normal) even with continued drug administration [7]

(5) Of your several searching questions, we may suggest an answer to one That hyperchloræmia persists during long term acetazoleamide treatment is not surprising, in view of the fact that the metabolic acidosis persists as long as the drug continues For although urinary acidity and ammonia return to normal, they do not (in the presence of the drug) *exceed* normal, and thus the initial base deficit is not repaired Chloride may be regarded as a "filler" to bring the anion level of plasma to normal in the face of low plasma HCO_3^-

TEACHING DEAF CHILDREN

SIR,—We know of several deaf children whose parents were told by E N T specialists that there was no urgent need for special school training until the children were five As the majority of doctors know, the 1944 Education Act says that all handicapped children should begin their education at two, and it is only because there are not sufficient school places available at present that this section of the Act is not being fully implemented

We find that children who begin school at four or five years are educationally very backward, compared with those who begin at two, particularly with speech training and language development The task of any teacher of the deaf is made infinitely more difficult when the child starts school late I think I can say that this is the unanimous view of all teachers of the deaf

It is therefore a disservice to the child and disappointing to the teachers to know there are still specialists who have not caught up with the 1944 Act

CHINESE MEDICINE

SIR,—I was very interested to read Dr James's article in your issue of May 21

Chen Chiu therapy or, as it is generally known in Europe, acupuncture has now a very wide following in France owing chiefly to the work of M Soulie de Morant, who was French Consul in China for some twenty years He was so impressed by the results which he saw of acupuncture that he studied it and went through the Chinese hospitals, and now has trained many doctors *in France* M Soulie de Morant died recently

I can speak from personal experience of its efficacy in many cases—in hæmorrhoids and in improving hearing due to adhesions of the eustachian tubes, for instance What impressed me most about this system was the method of diagnosis It is not necessary to tell an expert practitioner what is wrong with you he tells you!

While I was with M Soulie de Morant a lady came in suffering from very acute irritability He felt the pulses (there are supposed to be five or more pulses in each wrist, each corresponding to a different organ whereby they can tell the health of that organ) and he immediately remarked to the lady "I am not surprised Both your liver and spleen are enlarged and are pressing on the internal organs" He applied two needles and the result was almost instantaneous All the drag underneath the eyes disappeared and the result, I believe, has been lasting

M Soulie de Morant has written several treatises on acupuncture, and the work which he did is being carried on by many enthusiastic students

I have never been able to explain how the method works but it does work, and it certainly is capable of reducing hypertension

London, W 1

HERBERT A BERENS

STAPHYLOCOCCAL INFECTION IN THE NEWBORN

SIR,—The proper use of antibiotics is such an important issue for contemporary medicine that we hope that you will allow this friendly Border fray to continue for a little longer We should like to comment on three points raised by Dr Forfar and his colleagues in their letter of May 21

(1) On the question of the interpretation of their original article (March 19), we must plead guilty to the charge of having failed to qualify the term "infection" with the adjective "staphylococcal" throughout our letter the reason being that we were quoting almost directly from their article at the point where, under the subheading *Present Investigation,* they stated that "In Hospital E all clinical infections were treated with oral erythromycin In Hospital W clinical infections were *treated with the same dosage of erythromycin at the* same intervals" They also stated specifically that all cases of conjunctivitis were treated in the first instance with systemic erythromycin, and with local chloramphenicol only when this form of treatment failed They did later state, under *Discussion,* that "In most c of conjunctivitis systemic therapy is not indicat but this view was not repeated in the summary an seemed less consistent with their expressed objec preventing the development of serious sepsis, for w purpose a systemic antibiotic would appear to be n *rational Our own experience, of course,* has led u reject the routine use of any antibiotic in this prop lactic manner (as described in your issue of May 7)

(2) On the question of the relative merits *of ch* amphenicol and sulphacetamide drops in the rou treatment of conjunctivitis, we feel that an import point of general principle has been raised Leaving a the question of the doubtful value of in-vitro testing sensitivity to sulphonamides, we prefer to use sul acetamide to treat this relatively trivial form of infect because we know that at the present time no patie life, *threatened* by severe staphylococcal sepsis, depe upon his organism being sensitive to a sulphonam drug there are more potent drugs available, and ch amphenicol and erythromycin *are two* of them therefore feel it of the utmost importance to rese such drugs for potentially fatal infections It might fact be profitable to try out older and *simpler reme* again, such as normal-saline eye-drops

(3) On the question of the risk that babies who home with an unresolved clinical infection may spre resistant strains of staphylococci to the community, would only say that the problem is a much bigger than Dr Forfar and his colleagues suggest Numero studies have shown that up to 85% of normal babies *maternity* hospitals are carrying staphylococci of hosp strains in their noses, cord stumps, or conjunctival s by the end of the first week of life (we need only quo *the figure* published by Dr *Forfar* and his colleague their article of March 19, that staphylococci we recovered from 76% of the umbilical swabs taken) T carry their argument to its logical conclusion, they wou have to treat all these babies, and not only those w were clinically infected

---

[5] Bolsky H *New Engl J Med* 1953 249, 140
[6] Ruskin A *Arch intern Med* 1955 95, 24
[7] Leaf A Schwartz, W B, Relman W B *New Engl J Med* 759

We believe that at the present time the use of the more powerful antibiotics should be restricted to the minimum. If we cannot prevent the babies taking staphylococci home with them we can at least try to reduce the risk of their organisms being resistant to the drugs on which their lives and those of their household contacts may later depend

HEROIN

SIR—The Government have decided that supplies of heroin shall be withdrawn at the end of the year All practitioners realise the dangers of addiction to this drug but surely the addict obtains his supplies from different sources ?

There are three dangers in this legislation

(1) The profession will be deprived of a powerful drug which has a definite place in both medical and surgical treatment

(2) It will no longer be possible to treat established addicts with decreasing doses of heroin.

(3) Practitioners who use this drug will be tempted to buy a large quantity of heroin before Dec 31 for their future use.

This is the first occasion that it has been necessary to prohibit the use of a drug Surely the amount of addiction in this country does not warrant such a severe measure ?

W F W SOUTHWOOD

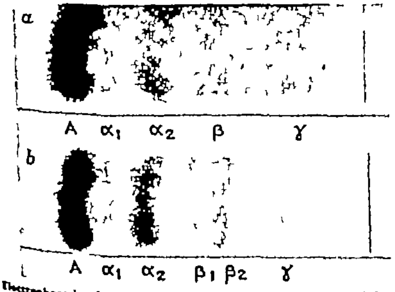
West London Hospital
London W 6

⁎⁎⁎ As was explained at the representative meeting of the British Medical Association reported on p 1218 the ban is being imposed by this country as part of an international effort to prevent heroin addiction We should prejudice the success of this effort if we dissociated ourselves from it —ED L

ELECTROPHORESIS OF PLASMA-PROTEINS

SIR,—In his letter of April 23 Dr Owen reported that under certain circumstances using a Veronal buffer for paper electrophoresis he has obtained a separation of the β globulin into two components This is contrary to the usual experience also shared by us that β-globulins travel as a single band in such systems when no other ions are added

We have found recently however that in some patients (see accompanying figure) heparin causes a splitting of the β-globulin band This phenomenon has been observed only when heparin was injected in the fasting state and hitherto we have found it only in sera from patients with severe diabetic angiopathy and the Kimmelstiel Wilson syndrome When heparin was given after a fatty meal no separation of β globulins occurred, and no separation was observed in post heparin sera from patients with recent diabetes mellitus or from non-diabetic patients with chronic kidney diseases



Electrophoresis of serum (a) before and (b) after heparin injection.

Aarhus, Denmark.

THE DEPARTMENT OF PHYSICAL MEDICINE

SIR,—I was very interested to read the report (May 28) of the annual meeting of the British Association of Physical Medicine.

It is a deplorable fact that at present patients can be treated only in central departments of physical medicine because only there could be found the requisite medical and technical staff and equipment.' This entails much loss of time in travelling and waiting by patients

At the inception of the National Health Service various alternatives were offered to the Minister of Health for setting up peripheral clinics staffed by qualified physiotherapists to avoid the anticipated difficulty of waiting lists, expensive hospital transport and harassed physiotherapists. The Minister saw fit to rebuff all these efforts Dr Fell it seems did not specify whose brains should be pooled to solve these problems.

Dr Cooksey voiced the concern of many at the shortage of physiotherapists May I point out one reason for lack of recruitment ? Parents see little advantage in educating their children at university level for three years when the eventual remuneration just does not compare with other professions and occupations.

LEONORA MASON

PROLONGED JAUNDICE

SIR,—I read with interest the paper by Dr Klajman and Dr Efrati in your issue of March 12 They refer to the condition described by Dubin and Johnson [1] and in their summary they emphasise that clinical examination revealed nothing abnormal except jaundice and slight enlargement of the liver

I would like to draw attention to a similar if not the same disease (or perhaps I should say condition) described in 1948 by Rotor Manahan and Florentin [2] In their cases the van den Bergh reaction was directly positive, and the blood bilirubin showed a considerable increase in hepatic or crystalloid bilirubin but there were no symptoms of obstructive jaundice the urine did not contain bile and the stools were normal in colour

I had the chance to observe the children of one of the families in this series In my paper [3] I said that the syndrome was marked by jaundice the accumulation of hepatic crystalloid bilirubin in the body and the absence of occlusion of the biliary passages or any other liver damage It was congenital and familial Although the first signs could be observed in early infancy it seemed that the jaundice became latent during infancy for some unknown reason but manifested itself again later and persisted throughout life The ætiology was completely unknown The liver disturbance was confined to bile metabolism

It has been said that this kind of jaundice is quite different from the familial non hæmolytic jaundice described by Dameshek and Singer in 1941 [4] I believe that the condition described by Dubin and Johnson and by Dr Klajman and Dr Efrati are similar if not identical and I wonder whether the disease really is a new clinico pathologic entity if it is in fact due to an inborn error of metabolism In that case one would expect the condition to be *familial and inherited* as we found it to

be As in the case described by Dr Klajman and Dr Efrati, in our cases the gall-bladder did not fill with opaque dye and the patients were in excellent health

Department of Pædiatrics, College of Medicine, University of the Philippines Manila — EUGENE STRANSKY

ENURESIS

SIR,—Following the recent correspondence, I wish to cite the following case, treated at the Liverpool Royal Infirmary, which seems to fall into the category of “ acquired relative nocturnal polyuria ” [1]

A youth of 20, an only child, was said to have first had nocturnal enuresis at the age of 10 He was referred to the psychiatric outpatient clinic after being fully investigated physically and “ having had every treatment except hypnosis ” He was accordingly treated by hypnosis and suggestion for some months but his condition showed only slight improvement During the past few months he has been treated with posterior lobe pituitary snuff (‘ Disipidin ’), as advocated by Hansen,[2] and improvement has been marked

The initial dose was gr 1 (60 mg) at night and this gave an immediate good result Five weeks later, without the patient’s knowledge, an inert snuff was substituted, and this was followed by a complete relapse Disipidin was restarted at gr 1½ (90 mg) at night and later increased to gr 2 (120 mg) The accompanying table illustrates the results

DRY AND WET NIGHTS PER TWO WEEK PERIOD DURING TREATMENT WITH DISIPIDIN

Wet	4	7	9	3	3	5	4	1	0	3	2	0	0
Dry	10	7	5	11	11	9	10	13	14	11	12	14	14
	Disipidin (gr 1)		A	(gr 1½)	Disipidin (gr 2)								

A = inert powder for last seven days of this fortnight Six of these nights were wet

Dr Poulton (March 19) points out that it is possible by bladder training alone to achieve control, even in the case of a patient excreting equal volumes by day and night, but goes on to say “ in general, ancillary aid must be brought to bear ”

The case I have described suggests that posterior-pituitary snuff, by increasing absorption by the epithelium of the renal tubules, might have a useful place in the treatment of cases classifiable as absolute polyuria and relative nocturnal polyuria

Rainhill Hospital, near Liverpool — MICHAEL J COSGRAVE

STERILISATION OF SYRINGES

SIR,—In your annotation of Jan 22 you state that “ autoclaving is unsatisfactory because the syringes have first to be taken apart ” This was challenged by one of us (W N R) in your issue of Feb 19, and in their reply of March 5 Dr Darmady and Dr Hughes state “ If Dr Rollason likes to carry out the simple experiment of placing dried spores in the bottom of the barrel with the plunger in position he will soon be convinced that autoclaving under these conditions is not desirable as a method ” Such an experiment has now been carried out by one of us (J G A) using the autoclaves in many of the hospitals in this area

The spores used were the same as those used by Dr Darmady and Dr Hughes—namely, those contained in “ green label ” earth as kindly supplied by Dr B W Lacey, of the Westminster Hospital, London These spores are more resistant than those of *Bacillus subtilis* as obtained from the National Collection of Type Cultures and are stated by Dr Lacey to be killed only after exposure to 115°C for fifteen minutes

All glass syringes (10 ml) were used, some of them being oiled The needles were not attached On two occasions the syringes were inside metal containers, care being taken that there was an opening in the container to allow the entrance steam In the other ten instances they were in glass tub and care was taken to ensure that the plug was permeab while in the autoclave The results obtained show very clear that an efficient autoclave is all important and that it w kill these spores in the assembled syringe at a temperature 120°C at a pressure of 20 lb for twenty minutes

One theatre autoclave was successful at 15 lb for fifte minutes The others have not been tested at this pressur Two rather old laboratory autoclaves were successful 20 lb for twenty minutes, but not at 15 lb for fifteen minute One old theatre autoclave was unsuccessful on two occasion at 20 lb for twenty minutes It has since been replaced by new one It is important to note that this old autoclav successfully killed spores of *B subtilis* (as obtained from th National Collection of Type Cultures) when used on a str of filter paper

The experiments show that autoclaving at a temper ture of 120°C at a pressure of 20 lb for twenty minute as stated in the M R C leaflet on the Sterilization, Us and Care of Syringes (1945) and quoted in the letter b one of us (W N R) (Feb 19), is a satisfactory metho of sterilisation of assembled syringes

J G ALEXANDER
Hull — W N ROLLASON

Obituary

CHARLES WILLIAM BUCKLEY

M D Lond , F R.C P

Dr Buckley, whose death we announced last wee was a leading authority on rheumatism, his grea experience being gained as a spa physician at Buxton Derbyshire

Born at Derby in 1884 and educated privately, h came to London with an entrance scholarship St Mary’s Hospital and qualified in 1898 In the earl years of the century he settled in practice in Buxton but it was not until 1912 that, after many unsuccessfu attempts, he obtained appointment to the staff the Devonshire Hospital for Rheumatic Diseases, for which he was to do so much and to which he brought so much renown He became M R C P in 1923, when general practitioners were made eligible for membership of the Royal College of Physicians, and after discontinuing general practice, he was elected to the fellowship in 1933

A fine clinician, Buckley communicated his knowledge on many aspects of rheumatism His writings, always immaculately presented, appeared at intervals over the years in many medical journals and textbooks His last article appeared in 1948, his last chapter in 1955, and both were completely up to date The subject which interested him most, and to which he contributed much, was ankylosing spondylitis The first of his papers on this disease, which at that time was seldom recognised appeared in 1932 , it was based on the study of 150 cases Rather surprisingly, he produced only one book—a handbook for the general practitioner entitled *Arthritis, Fibrositis, and Gout* His greatest contribution to the specialty was his editing, first of the Royal College of Physicians reports on rheumatic diseases, and later of the *Annals of the Rheumatic Diseases*—a journal founded by the Empire Rheumatism Council and subsequently adopted by many Rheumatic Associations both in Europe and in America

He was a member of many medical societies, both national and international He served on the scientific educational, and editorial committees of the Empire Rheumatism Council, and he held office as president of the Heberden Society and of the section of Balneology of the Royal Society of Medicine He was made an honorary member of the American Rheumatism Association in 1948 Among his academic distinctions was a lectureship in chronic arthritis and rheumatism at the Postgraduate Medical School of London When he left Buxton he was made a freeman of the borough

---

[1] Poulton E M , Hinden, E *Arch Dis Childh* 1953 28 392

[2] Hanson R E A S *Brit med J* 1954 i, 1038

Much as they respected him, his colleagues did not always find Buckley easy to get on with His stern appearance, and his sometimes rather pontifical manner could make him difficult to approach He was in fact a much shyer and more solitary man than was realised This was borne out recently when it was proposed to devote an issue of the *Annals of the Rheumatic Diseases* to commemoration of his 80th birthday though he reluctantly allowed his photograph to appear he forbade any further tribute to his life and works But to those of the younger doctors whom he considered anxious to learn he was kind and free from pomp, and he taught them magnificently His thoroughness and conscientiousness in the performance of his duties, his careful hospital notes written in his meticulous handwriting made a great impression on them Others of his qualities, again were appreciated especially by his associates in the town council where he was admired for his wit and skill in debate and for the breadth of vision and the underlying deep sympathy which accompanied his delightfully dry manner, and his incomparable ability to hold his own

Buckley's medical achievements are the greater when three things are taken into consideration First, during the years of his fullest activity few physicians in this country were at all interested in the rheumatic problems, and there were few rivals to keep him up to the mark. Secondly, he practised at a spa at a time when spas were unfashionable and were regarded with suspicion by members of the profession Thirdly not only did he practise in a spa but he took an active part in the affairs of its corporation (which owned the spa) being for many years a councillor and later an alderman and mayor in 1924–25 Yet he never claimed that spa treatment had any specific properties except perhaps in cases of persistent gout But he did believe and with good reason, that a spa was an excellent place in which to treat the rheumatic patient.

Apart from his medical and municipal activities he had many outside pursuits He was interested in archæology, he enjoyed his game of golf which he often played by himself or with members of his family He spent most of his holidays fishing and was for several years a member of the Flyfishers Club

Dr Buckley died at his home at Ashbourne in Derbyshire on May 28 His wife, formerly Miss Lilian Hughes, survives him with three daughters. Their only son who was a scholar at Eton died last year

HENRY ALLMAN LAVELLE

B.A., M.B Dubl

Dr H A Lavelle died at his home in Derby on May 25 at the age of 60 The son of Francis Lavelle an inspector of schools in Ireland he was one of a remarkable family of six of whom three brothers and one sister were medically qualified while another sister was a science graduate

Henry Lavelle himself entered Trinity College, Dublin as a sizar in 1914 and soon became known for originality of thought and action which he retained throughout his life After an attack of poliomyelitis in childhood he was severely handicapped by residual paralysis and although this did not prevent him from taking an active role in the defence of Trinity College during the rising in 1916 it did bar him from the Armed Forces. Instead he worked for nearly two years as an unqualified resident in general and mental hospitals both in Ireland and in England. As a result he did not qualify until 1920 when he came to the Derbyshire Royal Infirmary as a house-surgeon

In 1922 he entered general practice in Derby having married Evelyn Garnett who had been a house surgeon with him Within a year or two he had been appointed honorary obstetric physician at the Nightingale Maternity Home and honorary surgeon to the Derbyshire Hospital for Sick Children, and throughout his professional career obstetrics and the surgical diseases of children continued to be his main interests, although he never abandoned a large general practice and he was indeed a capable and much loved family doctor He was president of the Derby Medical Society in 1945 and until prevented from doing so by the illness which in 1948 struck him down and brought about his retirement from practice he hardly ever missed a meeting He frequently spoke in the discussions and could be relied on to contribute shrewd often racy and sometimes pungent comment.

Despite a very busy life he was extraordinarily well read in current literature both general and medical and he loved good conversation, which he spiced with his own subtle humour These qualities, coupled with his charm and his unconventional attitude towards many things, made him a delightful companion His interests were many and nothing gave him greater pleasure than driving his cars or tinkering with them for he was as capable with his hands in the garage as he was in the operating theatre Nor did he allow his disability to prevent him from following other outdoor pursuits, and he spent nearly all his holidays caravanning with his family usually in Cornwall where he was also able to sail and fish to his heart s content.

Henry Lavelle will be greatly missed in Derby He is survived by his widow and by two sons and two daughters One daughter is medically qualified and the wife of a Derby doctor and one son is a medical student

G F K.

ROBERT SKEOCH FREW

M.D Edin F R C.P

AT the age of 73, Dr Frew died on May 30 at Chipping Campden where he had lived since his retirement from the Hospital for Sick Children Great Ormond Street.

He was born at St. John s Newfoundland the son of William Frew and was educated at St. John s and at the Universities of Edinburgh and Berlin. Qualifying in 1905 he was house-physician at the Edinburgh Royal Infirmary and assistant to the professor of pathology His first paper published in 1909, was a contribution to the *Zeitschrift für physiologische Chemie* on the formation of lactic acid in muscle and his special interest in metabolic disorder continued when he became a pædiatrician Having worked as medical registrar at Great Ormond Street and as assistant physician at the East London Hospital for Children he was appointed in 1914 to the staff of King s College Hospital During the war he served in the Royal Army Medical Corps with the rank of major and he returned to Great Ormond Street as physician to outpatients He was also for many years physician to the Lord Mayor Treloar Cripples Hospital at Alton in Hampshire

Skilful in the handling of children Frew was also a very good teacher of undergraduates with a talent for exposition and simple classification In his investigations speculations, and innovations he was a man who thought for himself and made little attempt to reconcile his ideas with those of other people Early in his career he was a member of the Association for the Advance in Medicine by Research but as time went on he ceased to attend meetings of medical societies or to keep in touch with other people's work His *Disease in Childhood*, published in 1936 was largely the result of solitary reflection, and its emphasis on hyperphlebæmia as a cause of many of the disorders of early childhood and some of its other hypotheses, proved unacceptable

In the late war Dr Frew assumed heavy responsibility for administration at the Hospital for Sick Children and in order that he should continue to serve the hospital beyond the normal retiring age an additional appointment was created for him His son was killed in the war and he leaves a widow and a daughter

Births, Marriages, and Deaths

MARRIAGES

COHEN—WOLFSON.—On May [illegible] in London, Samuel I Cohen B.SC., M.D M.R.C.P to Vivienne L Wolfson M.B.

Notes and News

WORLD HEALTH ASSEMBLY

THE 8th World Health Assembly ended in Mexico City on May 27 On May 25 the programme and budget committee heard a statement about the Salk vaccine by Dr Frederick J Brady He said that the production of the vaccine in the United States might reach 58 million ml by the end of July, 1955 This would be sufficient to vaccinate 94% of all children from 1 to 9 years of age, which was the most susceptible period Production was expected to increase to 120 million ml by January, 1956, which would be sufficient to give two injections to approximately 60 million persons A variety of Bills were pending in Congress, including proposals to create a commission to plan and handle the distribution of vaccine, to extend the President's authority to establish rules governing control, distribution and production, and to finance the purchase of vaccine for free vaccination

The Assembly, which met under the chairmanship of Dr Ignacio Morones Prieto, health secretary of Mexico, adopted a budget of $10,203,084 for international health programmes throughout the world The Sudan was admitted as an associate member of the World Health Organisation bringing the total membership to 85

DOCTORS AND DENTAL EXTRACTIONS

THE question whether a doctor should extract teeth in an emergency was discussed at a recent meeting of the Lancashire Executive Council[1] Instances were given of children in severe pain being unable to get immediate attention A dental member said that there were not enough dentists and there would not be until the conditions of service and pay were improved Dentists had to consider other patients who had appointments, he added Mr J A Speed, clerk to the council, said that medical service was guaranteed under the Act but dental service was not He doubted whether a child's doctor could refuse to draw a tooth in an emergency In cases of difficulty, if the council's office was contacted something could usually be arranged

THE ENDOCRINOLOGY OF REPRODUCTION

THE first impression given by the May number of the *British Medical Bulletin*,[2] devoted to Hormones in Reproduction, may be one of detachment from human medicine For this there are two good reasons The first is that the physiological system is, generally speaking common to all eutherian mammals, and contributions to this fundamental scientific study have been made from all branches of biology—from zoology and animal husbandry as well as from medicine The second reason is no doubt connected with the pious and apposite reference in his introduction by the scientific editor, A. S Parkes, sc d , f r s , to his teacher, F H A Marshall, who " fifty years ago today, on 18 May, 1905," in conjunction with W A Jolly, read before the Royal Society of London a paper in which the rôles of the follicular and luteal hormones were first clearly recognised This symposium is at once a tribute and a report of progress in the subject in which Marshall was the British pioneer As Dr Parkes says " Rarely has a single subject of biological research blossomed so profusely in so short a time The fruit is now before us as an impressive body of knowledge festooned, as might be expected with loose ends of observation and deduction " This general biological approach has unexpected and stimulating aspects, as when one author illustrates hormonal effects in the ovary of the giraffe fœtus, or another remarks upon the " evolutionary oddity " of " the hypothermal scrotum—at best an inconvenient organ " The articles on chemistry and biochemistry of the hormones have on the other hand, a more orthodox approach, and may be recommended as a summing up of the present position in a subject of current therapeutic interest

In fact, every aspect of the endocrinology of mammalian reproduction seems to have been touched on , and, where they are not discussed, sources of information are indicated It is provocative of thought, to say the least, to read the only two purely clinical medical articles—Clinical Value of Hormone Estimations by Eleanor H Venning, and Hormones and Human Fertility by G I M Swyer—against the background of general biology provided by the other reviews The result may be to produce a humble frame of mind in the medical scientist, combined with some satisfaction that, despite disappointments, simple empirical approaches have yet been of some value to medicine

The British Council is to be congratulated on this production, in which all the eighteen contributors ranging from Amoroso to Zuckerman, not only originate within the British Commonwealth and work in Great Britain, but are acknowledged authorities in their respective fields

There is much talk these days of " population policy ", in this country we have a Society for the Study of Fertility and in America there is a Society for the Study of Sterility—a possibly significant difference in the direction of approach. But the study of these subjects, and any social policy which may be put forward, must be based on scientific knowledge, an all important part of which is the biological and medical basis reviewed in this number of the *British Medical Bulletin*

"ASSIGNMENT CHILDREN"

WHEN the United Nations International Children's Emergency Fund (UNICEF) heard that Mr Danny Kaye was thinking of going round the world they invited him to visit some children on the way , and the Motion Picture Industry collaborated with them in making a record of these visits, The children—of India, Korea, Thailand, Burma, and Japan—are some of those that UNICEF is helping by feeding them with America's surplus milk, healing their diseases, and teaching their mothers the elements of their craft This short film—it only lasts about 40 minutes—never puts a foot wrong Mr Kaye never lets it He himself is the least evident of the characters in the piece, he never gets a close up Most of the time all you see of him is a back, while the camera watches the sea of laughing faces confronting him, or a distant pied piper heading a running troupe of children , and all you hear of him is a sparing commentary without one touch of false emotion " A clown is a clown in any language," he says , but this clown turns himself into a ' feed," throwing the children into relief, giving them the chance to show their own story—their hunger, their confidence, their gaiety and stoicism, their undeserved disasters This is a most moving film, one which everybody should see , for, as Mr Kaye himself remarked, at the world première on June 3 " if the Motion Picture Industry or anyone else can help us to understand what is happening to children we may be further on the way towards understanding ourselves "

CENTENARY OF A SANATORIUM

IN the early 1850s the committee of the Brompton Hospital began to consider constructing a sanatorium On Oct 1, 1855, as the result of the committee's initiative the National Sanatorium for Consumption and Diseases of the Chest was opened at Bournemouth with accommodation at first for fifteen male and fifteen female patients This month the Royal National Sanatorium, as it has since become, has been celebrating its centenary In its hundred years of activity the death rate from pulmonary tuberculosis has fallen from nearly 28 to less than 2 per 10,000 population

YOUNG EATERS

Mr F Le Gros Clark has that invaluable possession, a perennially fresh mind He has been writing about nutrition for many years, and it might be supposed that he had exhausted every approach to even this many sided topic Not a bit of it in a new little book[1] written for the National Society of Children's Nurseries he has asked and answered the questions likely to occur to a mother with her first baby and very sensible questions they are, and most refreshingly answered Instead of plunging her into a morass of unfamiliar terms and weighing her down with the latest news of vitamins, he begins with a short outline of the physiology (though that word is never mentioned) of feeding and growth, drawing her attention to three components of her baby—his muscles and organs, his bones and his fat This naturally leads to a longer account of each of the three, and of the foods which help to make them Protein naturally gets a good deal of space, and Mr Le Gros Clark explains how a mixed diet can supply the various amino acids (a word used only once, at the end of the explanation) needed by the body, which then selects and rearranges them to suit itself This he does by

drawing the analogy of a bead bag from which beads may be taken to build up another bag of a different pattern. He writes of the calcium-containing foods which build the bones the energy stores of the body in the liver and muscles (the word "glycogen" is not mentioned) and in the fat deposits the nature of common foods emphasising that most of them contain more than one of the three main components and finally the four main vitamins—not as "food" but as "traffic controls" organising the materials from our food into the structure of our bodies. In the same lucid and simple way he discusses weaning and table manners unobtrusively reminding the mother in every sentence that she will be dealing not with a "model baby" but with an individual of strong personal views.

The book is described as a short introduction for the use of student nurses but well though he has served the nurses it is the ear of the mother which Mr Le Gros Clark has hoped and deserves, to catch.

GENETIC CHANGES DUE TO RADIATION

SPEAKING lately at the University of Chicago Dr Willard Libby a member of the U.S. Atomic Energy Commission, read the following statement prepared by members of the commission's advisory committee for biology and medicine[1]:

> "The radiation produced by fall-out from atomic weapons ts as well as from present and future peaceful applications of clear energy will result in additional mutations in human genes. The number of these cannot be estimated accurately at this time. the current rate of irradiation from fall-out among the four llion children born each year in the United States perhaps from a ndred to several thousand may carry as a result of this irradiation mutated gene.
>
> "At most a small percentage of these genes will produce any noticeable effects in the first generation. Only slowly over hundreds years will the majority of these radiation induced genes become parent, in a few individuals at a time usually by causing a less n normal development or functioning of the person concerned will be impossible to identify these individuals among the large mber of similar ones affected by genes already present in the pulation due to accumulated spontaneous mutations.
>
> "No measurable increase in defective individuals will be observ at any time as the result of current weapons tests since the w radiation-induced defectives will not change measurably the mber of about forty thousand defectives who will occur spon eously among the four million births of each year in the United tes. It may be pointed out that no significant change in the rcentage of malformed children has been observed among those nceived after the war whose parents had been exposed to the mic bombs in Hiroshima and Nagasaki.
>
> "The foregoing conclusions apply only to the genetic effects weapons tests carried out at the present level and the foreseeable ce-time uses of atomic energy. The genetic effects of a generalised ar war would be one of many catastrophic consequences of such saster."

MANAGEMENT OF LABOUR

A NEW film made by Dr Grantly Dick Read and entitled *Childbirth without Fear* is not so much a means of instruction as of propaganda. But it is none the less impressive for that. The deliveries of four unselected mothers are shown quite kly and the expressions on these women's faces are memorable. e is an introduction to each case by Dr Read and brief pses of the earlier stages of labour—sufficient however ggest the general scheme of management. There is little iption of the antenatal preparation of the mothers—a wise sion in a short film with little time to spare especially antenatal preparation has been over publicised at expense of the more important subject of management ng labour.

he question arises, as it always does with such films for m is it intended? This one could usefully be shown to ical groups as a prelude to discussion. It could also ently well be shown to expectant mothers and their bands provided the showing was well supervised and oduced for there is nothing in it that is not encouraging. the other hand some teachers might hesitate to show it to ents because there are points in technique that are open isagreement.

ainless *Childbirth* is a film on the work of Dr Fernand naze made for showing to mothers as part of Dr Lamaze's gramme of antenatal preparation. It would not be suitable that purpose in this country since it shows a distressed mipara in the second stage. The most impressive point de in the film is that the labouring mother must never be t alone—trained or untrained—for it is in loneliness that the rors and incoordinations of behaviour in childbirth appear. Lamaze does not use only doctors and midwives the n shows an aide or orderly, trained in the method helping the mother to concentrate on her breathing rather than on her discomfort.

This film is suitable for midwives, students and physiotherapists. The teacher showing it needs to make it clear that the techniques of delivery are not an intrinsic part of the method but are those commonly practised in France. Apparently in the Soviet Union where Dr Lamaze learnt his technique ideas about the management of delivery are similar to those in this country.

PHILADELPHIA CHILDREN'S HOSPITAL

THE Children's Hospital in Philadelphia was established in 1855 and during the centenary celebrations last week[1] a block and gavel made from the wood of a plane tree which grew in the garden of the Hospital for Sick Children Great Ormond Street were presented to the hospital by Dr Alan Moncrieff Nuffield professor of child health in the University of London, who was a special delegate and spokesman at the proceedings for Great Ormond Street and other British children's hospitals. He recalled that the two institutions in London and Philadelphia were the first children's hospitals in the English speaking world (Great Ormond Street was just three years older).

Royal College of Physicians of London

Dr K. M. A. Perry is to deliver the Ernestine Henry lecture at the college Pall Mall East S.W.1 on Tuesday June 21 at 5 P.M. Dr Perry will speak on Pulmonary Diseases Associated with *Metallic Oxides*.

Dr Ian McLean Baird working in the department of therapeutics at the Royal Infirmary Sheffield has been appointed Leverhulme research scholar of the college for 1955.

Royal College of Surgeons of England

Faculty of Anæsthetists.—At a meeting of the board of the faculty on June 1 Dr Frankis T Evans was elected dean and Dr R F Woolmer was re-elected vice-dean for the ensuing year.

Royal College of Surgeons in Ireland

At a meeting of the college on June 6 the following were elected:

President Ian Fraser, vice-president A B Clery *other* members of council J F L Keegan, R. A Stoney J F L. Devane A A McConnell, T O Graham William Doolin Frederick Gill T G Wilson M P Burke R R Woods S F Heatley J H Coolican T A Bouchier Hayes, N A Kinnear D J Riordan F W L. Thompson F A J M. Duff D W Montgomery J M M Curtin.

Osler Club of London

To mark the centenary of the birth of Stephen Paget the club is to meet jointly with University College Medical Society at University College Gower Street W.C.1 on Thursday June 16 at 8 P.M. when Prof G P Crowden will speak on Pioneers in Experimental Physiology and Dr J H Baron on The Brown Dog of University College.

Royal Sanitary Institute

The following are among the forthcoming sessional meetings:

London.—Mr P G Shute: Rôle of Mosquitoes in the Spread of Myxomatosis and Suggestions for their Control; at 2.30 P.M. on Wednesday June 22 at the institute 90 Buckingham Palace Road S.W.1.

Oldham.—Dr J T Chalmers Keddie: Care of the Mentally Ill and Mr H V Cas: Housing Repairs and Rents Act 1954; at 10 A.M. on Friday July 8 in the assembly room, Town Hall.

London.—Dr J D Kershaw: Public health Nurse of the Future; at 6 P.M. on Wednesday, July 13 at the institute.

Taunton.—Dr Hugh Morrison: Changing Face of the Control of Infectious Disease and Sir Arnold Waters: Taunton Sewage Scheme; at 10.30 A.M. on Thursday July 21 in the council chamber Shire Hall.

Medical Society for the Care of the Elderly

At the annual meeting of this society on May 7 the following were elected to the executive committee:

President, Lord Amulree; hon vice-presidents Dr J H Sheldon and Dr E L Sturdee; hon treasurer Dr W Morton; *hon secretary* Dr A. N Exton Smith; hon deputy secretary Dr P Arnold, other members Dr J Agate Dr O T Brown Dr K J G Milne Dr L Nagley, Dr O Olbrich *Prof* R. E. Tunbridge Dr M. Warren, and Dr T S Wilson.

Hypnotherapy Group

At a *meeting* at 1 Wimpole Street London W 1 on Wednesday June 15 at 8 P.M. Dr H J Shorvon will discuss the Use of Drugs in the Induction of the Hypnotic State.

Royal Appointment

Air Commodore Denis Aymard Wilson has been appointed an honorary surgeon to the Queen in succession to Air Vice Marshal E D D Dickson, who has retired from the Royal Air Force

Collegium Internationale Allergologicum

The second symposium of the Collegium, dealing mainly with Migraine and Vascular Allergy, is to be held in Basle on July 3–8 The president is Dr D Harley, 19, Queen Anne Street, London, W 1 , and the secretary is Dr P Kallós, Sundstorget 3, Helsingborg, Sweden

Commonwealth Bursaries

Awards under the Royal Society and Nuffield Foundation Commonwealth bursaries scheme include the following

Dr A A. Kinnear *Institute for Pathology, University of Pretoria*, to study endocrinological techniques at Birmingham from July to September, 1955

Dr. J H D Millar neurologist Royal Victoria Hospital, Belfast, to study electrocorticography at the Montreal Neurological Institute from September to November 1955

Panel on the Composition and Nutritive Value of Flour

The panel set up by the Government, under the chairmanship of Lord Adrian, P.R S , to investigate the composition and nutritive value of flour (see *Lancet*, May 14, 1955, p 1021) has held its first meeting Persons or organisations wishing to submit evidence are invited to send this in writing to the secretary, Miss B M Shedden, 10, Whitehall Place, London, S W 1, by July 9

MENTAL HEALTH
DESPITE
MENTAL RETARDATION *

A. F ALFORD
C.B.E., M B Brist
SENIOR MEDICAL OFFICER, MINISTRY OF EDUCATION

MENTAL deficiency is not an illness or a disorder of mind, but rather an arrested or incomplete development of brain, usually from birth leading to a diminution of intellectual powers relative to the chronological age † Unfortunately children who are born with this deficiency of mental powers receive less sympathy and understanding than children who are physically handicapped Those who suffer from a disability which can be *seen* usually receive warm hearted pity, even though the nature of the handicap may not be fully appreciated or understood But those who suffer from a mental retardation rather tend to raise in the public mind a sense of repulsion and even an emotional dislike This attitude is due, primarily to a lack of knowledge about these children as regards both the genesis of their retardation and its effect on their intellectual and emotional well being the possibilities of the child developing such powers as he has and becoming a useful citizen are ignored

This present attitude of so many is greatly to be deplored For if mental defectives are not received naturally and without bias in the community but are shunned or treated as outcasts, their mental health suffers leading frequently to introspective emotional disturbance or to aggressive antisocial behaviour

The Parents Feelings

Parents attitude towards their defective offspring may leave even more to be desired The parent-child relationship should be the same as in normal families, and yet often, particularly where the parents are intelligent is clouded by a deep sense of guilt because they imagine that the handicap is their fault, or that they being punished for past misdeeds

This sense of guilt is chiefly based on lack of knowledge the possible causes of mental deficiency Thirty or ty years ago mental deficiency was thought to be caused entirely by heredity if a child was mentally defective it was taken as a sign that his parents—or their parents before them—were defective too Since those days, however it has become abundantly clear that, though heredity remains a prime factor there are other causes which produce subnormality In families unimpeachable heritage mentally defective children found. Indeed in most gatherings of professional and intelligent people there is likely to be at least one family containing a mentally subnormal child. Proof of causation still evades us Certain postnatal illnesses such as meningitis and accidents are readily accepted causes But many theories have been advanced which implicate among other things endocrine deviations or biochemical reactions in utero the rhesus factor and natal asphyxia and cerebral damage during birth Although none of these theories would explain more than a small fraction of these indeterminable cases, it does bring consolation to parents and removes their sense of guilt to know that their child may be as he is through causes other than heredity

But, even if this sense of guilt is lessened or removed parents find it difficult to accept a defective child in the family The less intelligent parents frequently may not acknowledge the presence of the disability at all It is not easy, even for intelligent parents to understand that a child can have a world which is different in any way from their own, that his perspective and outlook cannot be the same as theirs, and that the future does not hold a cure for an innate mental disability They do not realise that the lower the intelligence the greater the shrinkage of the child s world until, in the lowest grades the world is the child s immediate environment, the part of a room or garden in which he happens to be at that moment. They are unwilling—subconsciously, if not consciously—to accept that a defect of mind remains throughout life Thus, false hopes are aroused which, when they are dashed, lead to resentment and even despair

Such feelings and the sense of guilt as well can create a vicious circle An unnatural barrier is set up between parent and child which not only prevents a mother experiencing the full joy of motherhood but may also prevent her showing any of the love she feels for her child This can have a disastrous effect on the emotional development and well being of the child whose reaction in turn may loosen the bonds of mother love to such an extent as to bring about partial or even complete rejection of the child

The point to be driven home to the public at large, as well as parents is that every child who is handicapped either in mind or body should be looked upon not as a defective but as a normal child, with a deviation from normality in one particular respect This positive approach tends to focus attention on potentialities instead of imperfections

When a child is born who is obviously mentally defective what should be said to the parents? The parents are keyed up physiologically and emotionally, and such a child is a bitter anticlimax to their hopes and expectations It is not right to leave them in a state of ignorance for long for the sooner they realise their misfortune the better they will be able to cope with the problem If such knowledge is withheld too long the mental health of the parents and subsequently of the child will often suffer more damage the late repair of which becomes increasingly more difficult—as experience has proved over and over again But the information must be given judiciously, tenderly and with much sympathetic understanding and patience There is more than one way of saying the same things care must be taken to use the way which will help the individual most to accept what has happened and to make the best of it

Later on if the parents have a sense of guilt or despair and a vicious circle is set up it may be broken by the family doctor or any other person who is able to approach the problem with wisdom understanding and sympathy He can help the parents to face reality by explaining what they feel as simply as possible by being willing to listen and by answering their questions, however indefinite and vague Once the agitation of the parents' minds has been calmed by the acceptance of the situation, their mental health improves and that at once has a favourable effect on their child

Education and Self-respect

The variability of intellectual deficiency is infinite But whatever the intellectual level the aim must always be to nurture and develop to the fullest extent in early life the intelligence there is so as to enable a child to live a life to the limit of his powers and to equip him to

---

World Federation for Mental Health A paper read last August at Toronto before the Fifth International Congress on Mental Health under the title Some of the Mental Health Aspects of Mental Deficiency

Mental deficiency is not defined in the same way in all countries In England and Wales, since the Education Act of 1944 the term has referred only to those children who by reason of a mental disability cannot be educated in schools. Those who can be educated in schools but need some special help are classified as *educationally subnormal* and that is the group with which this paper is chiefly concerned take his place, however lowly, in the world around him, and to make him acceptable to his fellow men

If an attempt is made to drive a child too far, he will feel frustrated by his failure and may well sink below the level he could otherwise comfortably reach If a child is not stretched adequately, then he will stagnate and lose his self-esteem and respect A child who lives fully up to his intellectual capacity has also gone a considerable way toward the contentment and happiness which are the foundation of mental health

Furthermore, the retarded child must have within him a sense of self-respect, if his mental health is to flourish Many components, acting in unison, help to instil this self-respect Uninhibited mother-love and good family relationships, full development of intellectual powers leading to achievements both in thought and action, fostering of independence, belief in and realisation of innate abilities, and, above all, acceptance by others—all exert a tremendous influence on the growth of self respect Obscured by mental deficiency, this may appear of little consequence to others, but to the child it is vital and extremely satisfying It is not brought about by development suddenly or by concrete effort on the part of others It waxes imperceptibly as the early years pass, chiefly through the external influences and guidance of others, until self-respect prevails Then lies ahead a life full of promise

A child can be helped to develop his mental powers to their fullest extent if he is given the right education and training For this it is essential to have a sound knowledge of the diverse combinations of attributes and of the variations of mental processes in the intellectual make up of mentally retarded children This knowledge can only be acquired by experience, based initially on a profound understanding of normal children and of the very wide limits of normality For, until this has been done, the significance of deviations from normality can neither be fully appreciated nor assessed Because each child is an individual, there are no easy rules which govern the understanding of these retarded children Every one must be considered as a separate entity, and his needs met in such a way as to encourage the promotion of his good mental health

Although a mentally retarded child will in intelligence be well below the average for normal children of the same age, he will have some mental qualities which range themselves above or below his general level What counts is that he has some qualities above *his* average, the general average does not matter Further, it is essential to remember that these children do not all possess the same characteristics Not only do they differ in intelligence, but at each level they also differ in temperament, emotional stability, and, above all, in upbringing and home background The results of these differences show themselves in uneven development They do not have poor memories for everything, they remember well only that which they comprehend or which has taken their fancy They may be able to repeat with ease simple poems or hymns, but be unable to recall anything of a lesson which was over their heads They can often concentrate well on something which interests them and yet be scatterbrained where academic subjects are concerned Sometimes, where written work is not required, they may approach closely to the interests and abilities of normal children in, say, handicraft or observation of Nature, in singing or physical movement There is scarcely one who has not some relatively strong point capable of being utilised by a watchful teacher as a basis for wider and more fruitful progress It is seldom that there is complete apathy, denying one a starting-point on which to build, but the building is a highly individual process which cannot take place in large groups If they are to advance, individual methods are

A sense of achievement is of immense importance to these children Every one of us derives great satisfaction from the accomplishment of a task, and the more difficult it has been the greater will be the satisfaction In mentally defective children the satisfaction secured through any achievement is always profound and it may be out of all proportion to the nature of the task It brings with it, as a natural sequence, a sense of mental well being, the corollary of good mental health On the other hand, while nothing succeeds like success, nothing is so devastating to the mental health of a defective child as to offer him lessons which are beyond his powers of comprehension If these are given, frustration, irritability, impatience, and many other manifestations of unsatisfied achievement will show themselves, and thes may be the seeds of emotional disturbances or of anti social behaviour later, which every effort should b made to prevent Hence, in the field of education teacher should concentrate from the start on the abilities an aptitudes which are above the child's average an should give lessons and tasks which are within the child' compass This, of course, means that the education mu be related more to the level of intelligence than t chronological age

Social Adjustment

Once action has been taken to secure appropriat education for a mentally subnormal child, results, as rule, are quickly apparent They are obtained mo rapidly where the change in environment is greate —for example, when a child is transferred from a ordinary school with large classes, where the teacher h little time for him, to a special school which caters f children of his intellectual level in smaller groups Th first change is usually in behaviour, for most teache realise that without social training there is likely to little progress in the more formal aspects of educatio They therefore concentrate at first on making the chi feel secure, on demonstrating that adults are rea interested in him, and on making it clear that they not judge him only by his success or failure in sch work Children with appalling histories of destructivene delinquency, tempers, aggressiveness, or truancy ha settled down quickly under a new régime and after t first few weeks have given no trouble at all After t improvement in conduct comes a blossoming of t personality, often accompanied by improvement carriage and physique, increased weight, and bett complexion The children become more agreeable to li and work with, they settle down with increased se confidence and self-respect to tackle their school wo and to use their intelligence, meagre though it may b to the best advantage The girls can be taught t appreciate and to develop habits of cleanliness and ord in the home, whilst the best learn to do some of t duties which fall to the lot of the housewife Bo usually have some instruction in practical work wh sometimes leads on to a skilled craft, but which, in a case, contributes towards the development of gener handiness The great justification for this régime i however, its success in making these children more social acceptable and adaptable

The social training of these children is of immens importance and of far more significance to them th mere educational attainments The extent to whi they are accepted as agreeable individuals by and in community is directly proportionate to the degree o their social adjustment A boy who is cheerful, willing and obedient, and yet perhaps unable to read or write will be accepted, whereas another who can do both relatively well, will be shunned or disliked on account of his lack of social qualities This attitude of the community has a direct reaction on the mental health of each boy The former boy feels that he has fulfilled his main ambition of being somebody in the eyes of others, thus giving him a sense of citizenship, and above all, of usefulness The latter boy has a feeling of failure and frustration or grievance and ill will against society, all of which breed discontent and unhappiness leading to emotional difficulties and maladjustment and perhaps even to delinquency and crime

In order to inculcate a sense of good mental health in mentally defective children several fundamental conditions must be fulfilled The most vital one is that the child must be brought to accept good social standards principles, and customs through education and training within a suitable environment Environments shape the individual; everyone can be affected by his environment be good or ill An unsatisfactory atmosphere produces an unsatisfactory person

The part that associates and companions play is also of much significance As the mental powers of a child are reduced so are diminished his powers of appreciation of right or wrong or of deciding things for himself He is easily led, he is swayed readily by others and he is apt to do things without realising their import He becomes very responsive to the influences, for good or evil, of those around him If his associates have low moral principles or delinquent propensities their influence on him is corrupting and he may easily succumb to their wiles and depravities His own mental health will suffer sooner or later as a result of discredit and disgrace leading to a declining self-esteem On the other hand if his companions are honest and of good character he will respond just as readily Through spending his time in a good atmosphere his mental health will profit Every effort therefore, should be made to ensure that so far as is possible these children are shielded from unsavoury associates.

Employment and Contentment

After education or training has ended employment has a direct bearing on the mental well being of these children They have an urge to be like others to be able to do things and above all, to have a job which earns them money Suitable employment is not always easy to obtain but when it is found to fit a young person his satisfaction is very real and he feels that he has proved his worth his independence and his usefulness Lack of intelligence is not by any means a bar to gainful employment In many of the unskilled and semi skilled occupations of modern life what counts in obtaining and retaining a job is not so much specific skill, literacy or information as steadiness reliability honesty and the ability to get on well with workmates and the foreman—in fact qualities of character and social development which can be acquired even by those of poor intelligence if they are well taught and are not discouraged by being forced to attempt what is beyond them. Because of their mental deficiency discontent or dissatisfaction about the relative lowliness of a job or the poorness of the pay does not arise He does not mind incessant repetition of the same action or activity it is something which has to be done by someone and *he* can do it. But if he is to enjoy his work to the full others around him must be aware of his limitations and must be willing to be tolerant kind and understanding

To sum up the ultimate aim with these children should be to make them happy and contented. The starting point is to regard them as normal children with an intellectual deviation They can be helped by social training and education to live a full life within their limitations giving them a sense of satisfaction worth and usefulness. With happiness will come mental health and a child who has good mental health even if he is mentally defective is an asset to the community and therefore to the country It is a challenge to everyone to help all mentally defective children to achieve the mental health which is the birthright of every human being

---

GLUTAMIC ACID IN HEPATIC COMA

J M. WALSHE
M.A M.B Camb M.R.C.P
From the Medical Unit University College Hospital London

RECENT research into the biochemistry of hepatic coma has directed attention particularly to disturbances of nitrogen metabolism

Previously I have pointed out (Walshe 1951) how disturbed metabolism of amino acids might inhibit the metabolism of glutamic acid in the brain, leading to accumulation of intracellular ammonia

Other workers have studied blood ammonia levels in hepatic coma (Schwartz et al 1953 Traeger et al 1954 McDermott and Adams 1954 Bessman et al 1954 Singh et al. 1954 Riddell and McDermott 1954, Sherlock et al 1954) Analysis of the published results shows great discrepancies in the values given for normal blood 'ammonia levels in the different groups and though the blood ammonia" level is usually raised in patients in hepatic coma or pre-coma, there is no more than a fair correlation between this and the state of consciousness It has been established however that ammonium salts and ammonium ion-exchange resins when given to *patients with advanced hepatic cirrhosis, may produce a* syndrome closely mimicking hepatic coma (Van Caulaert et al 1933, Fuld 1933 Gabuzda et al. 1952), and intravenous ammonium chloride will produce convulsions in rabbits—an action prevented by glutamic acid (Sapirstein 1943)

In a preliminary communication I described the results obtained with large doses of glutamic acid given either intravenously or by mouth to patients in hepatic coma resulting from chronic liver diseases (Walshe 1953) Five episodes of coma in 3 patients were treated with glutamic acid, and the results were sufficiently encouraging to merit further study

Subsequent reports on the use of glutamic acid in hepatic coma have been conflicting Some workers confirm the beneficial action in patients with chronic liver disease (Priest et al 1953 Whitehead et al 1954 Riddell and McDermott 1954 Walley 1954 H Blalock jun personal communication) whereas others have not been convinced of any benefit (Singh et al 1954 Davidson 1954, Sherlock et al 1954) There appears to be general agreement that, in the coma of acute hepatic necrosis, glutamic acid does not alter the course of the illness (Calvert et al 1954 Whitehead et al 1954 Riddell and McDermott 1954)

Since my preliminary communication in 1953 a further episode of coma in 1 of the original cases and episodes of coma in 4 further cases of hepatic cirrhosis and in 2 cases of massive hepatic necrosis have been treated with glutamic acid in this hospital Glutamic acid appears to influence favourably the coma of hepatic cirrhosis but not that of massive hepatic cirrhosis.

Case reports

HEPATIC CIRRHOSIS

Case 1—A man aged 60 who admitted to considerable spirit-drinking over many years, complained of losing weight for six months and increasing jaundice for one month There were no associated constitutional disturbances.

On examination he was deeply jaundiced, his spleen was impalpable and his liver dullness was much reduced to percussion; but fœtor hepaticus was present The protein-flocculation tests were strongly positive and the serum albumin level had fallen to 3·0 g per 100 ml The prothrombin concentration was too low to allow needle biopsy of the liver to be done with safety

Treatment and course—With rest in bed and adequate diet the patient's condition improved considerably and he left hospital almost anicteric after a stay of ten weeks. Three months later he was deeply jaundiced and mentally confused ascites was present he was extremely drowsy and his tendon jerks were very brisk, but he had no ankle clonus and the plantar responses were flexor. Oral glutamic acid 20 g. daily was started, and this coincided with a rapid improvement in his mental condition. After three days glutamic acid was withdrawn, and within twelve hours he became confused and incontinent of urine. Glutamic acid was restarted by mouth, and in the next forty-eight hours he returned to normal consciousness. Withdrawal of glutamic acid was again followed by coma within twenty four hours, with increased muscle tonus in the legs and bilateral extensor plantar responses. A slow intravenous infusion of sodium glutamate was started, 17 g. being given over eight hours. At the end of this time the patient was conscious and could answer simple questions, and the plantar responses had reverted to flexor. Maintenance doses of oral glutamic acid were given, but despite this he returned through confusion to coma during the next five days. After three days' coma he was given intravenous sodium glutamate 46 g. in twenty four hours; at the end of this time he could answer simple questions but was drowsy and resented interference. No glutamic acid was given after this, and the patient lapsed into coma and died three days later.

Necropsy revealed advanced diffuse fibrosis of the liver, which weighed only 840 g.

Case 2.—A man, aged 56, had been in good health until a year before admission, when he began to feel vaguely unwell and lost his appetite. After eight months he had a large hæmatemesis, which necessitated admission to his local hospital, where he was transfused and hepatic cirrhosis was diagnosed. After his return to work he became jaundiced and noted swelling of his legs and abdomen. There was a history of considerable drinking of beer and spirits during the war years.

On admission to University College Hospital he was mildly icteric and had multiple vascular spider nævi, ascites, œdema of the ankles, and fœtor hepaticus. There were no abnormal signs in the central nervous system (C.N.S.).

Treatment and course.—A fortnight after admission he had a very large hæmatemesis and, despite a transfusion of 6 pints of blood, passed into deep coma, with knee and ankle clonus and bilateral extensor plantar responses. There was then gross amino aciduria. After twenty-four hours in deep coma his condition was deteriorating and he was therefore given sodium glutamate 35 g. intravenously in twenty four hours. Consciousness was returning by the end of this time and was normal after a further twenty four hours. A month later he had another very large hæmatemesis and died before treatment could be started.

Necropsy showed that his liver was deeply scarred by dense bands of fibrous tissue and weighed 1200 g.

Case 3.—A man, aged 38, had been in good health until four years previously, when his abdomen and legs began to swell. He was admitted to hospital, and hepatic cirrhosis was diagnosed. His symptoms cleared completely after treatment by rest in bed and a high protein diet. He remained well for four years until December, 1953, when he was admitted to University College Hospital after having a hæmatemesis. He was found to have hepatic fibrosis and portal hypertension. While in hospital he had two further hæmatemeses on consecutive days and, despite adequate blood replacement, became comatose. He had a strong fœtor hepaticus.

Treatment and course.—After a day in coma he was given sodium glutamate 23 g. in eight hours, and four hours later he had regained consciousness and was mentally alert and rational. The following week he was sufficiently well to have an operation for splenectomy and lienorenal shunt. He remained in good health for six months, at the end of which he had yet another hæmatemesis followed by the development of a precomatose state and a raised blood-" ammonia " level (175 µg. per 100 ml.). His condition improved with glutamate therapy, and the blood " ammonia " level returned almost to normal (75 µg. per 100 ml.). Later there was an episode of severe rectal bleeding, from which he died.

Necropsy revealed thrombosis of his lienorenal shunt and his superior mesenteric vein, and infarction of much of his small bowel.

Case 4.—A woman, aged 39, had had an illness with abdominal pain and jaundice six years before she was first seen in University College Hospital. Two years after her first symptoms she developed ascites and œdema. The diagnosis of cirrhosis of the liver was confirmed by needle biopsy. At first the retention of fluids was controlled by ion exchange resins and a low salt diet, but later paracentesis abdominis had to be resorted to with increasing frequency. In August, 1954, forty eight hours after a routine tapping she became drowsy, complained of severe anorexia and headache, and developed a severe irregular tremor of her hands, with ankle clonus and bilateral extensor plantar responses. Fœtor hepaticus was not detected. Hepatic coma appearing imminent, she was given sodium glutamate 23 g. by mouth in the next two hours. Next morning (ten hours later) she was alert and had lost her abnormal neurological signs. This improvement was not well maintained, and a maintenance dose of sodium glutamate 23 g. by mouth daily became necessary. However, after a further four days the abnormal neurological signs returned and she became comatose. Sodium glutamate 30 g. was given intravenously, and she became rousable and able to answer simple questions. Treatment was discontinued because it was now clear that it could produce no lasting benefit, and the patient died thirty six hours later in deep coma. Necropsy was refused.

Case 5.—A man, aged 46 (case 1 of Walshe 1953), who also had chronic ulcerative colitis, had already had one episode of hepatic coma treated with sodium glutamate in 1952. Since that time he had kept in fair health until January, 1954, when, after an exacerbation of his colitis, he had a severe rectal hæmorrhage; he was admitted to hospital precomatose, with fœtor hepaticus and other signs of hepatic failure. Immediately after admission he was given a 3 pint blood transfusion, but his condition continued to deteriorate, and he became comatose. During the next twenty four hours he was given sodium glutamate 46 g. by slow intravenous infusion, and he had fully regained consciousness by the end of this time. He has remained in fair health during the following 9 months.

Case 6.—A woman, aged 30, was admitted in deep coma. She had apparently been unwell with nausea and vomiting for a month and had been jaundiced for two weeks. She had been in coma for about seventy two hours before her admission. She was deeply jaundiced, her liver dullness was reduced, her pupils were dilated, she was very restless, and ankle clonus and plantar responses were present. Treatment was directed to maintaining the fluid and electrolyte balances, and calories were supplied with 25% glucose solution; sodium glutamate 23 g. was given daily. There was no response to treatment, and the patient died on the third day.

At necropsy the liver was found to be severely necrotic; it weighed 800 g.

Case 7.—A woman, aged 45, with hepatic necrosis and fœtor hepaticus, was admitted in February, 1954. During the next ten days very careful control was kept of the fluid and electrolyte balance, calories were supplied by 25% glucose drip into the superior vena cava, and sodium glutamate 23 g. was given daily. After the first 23 g. of glutamate she could answer simple questions, but this improvement was not maintained, and there was no further apparent response to treatment before her death. For further details see Challenger and Walshe (1955b).

Summary.—4 new patients with chronic liver disease were treated with sodium glutamate,* either by mouth or intravenously, each for one or more episodes of hepatic coma or pre coma. 2 of them responded well. 1 of these left hospital in fair health to die later of mesenteric thrombosis, and the other had a good initial response but died later of hæmorrhage from œsophageal varices. The remaining 2 responded briefly only to die later of progressive liver failure. 1 of the 3 patients reported earlier (Walshe 1953) was treated in a second episode of coma and again responded. 2 cases of massive hepatic necrosis did not respond to treatment with glutamic acid.

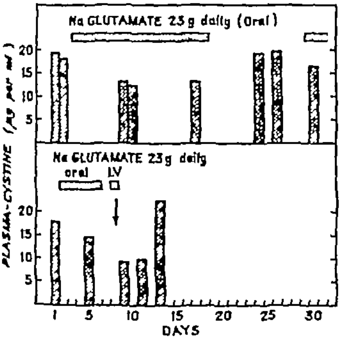
Special Investigations

Metabolism of Amino acids

The metabolism of amino-acids was studied by paper chromatography in 2 cases of hepatic cirrhosis and in both cases of massive hepatic necrosis. In both cases of cirrhosis detailed studies showed a definite abnormality of the pattern of amino acids in the plasma during coma,

---

* When given intravenously either the monosodium salt of L (+) glutamic acid or a mixture of the sodium and potassium salts in the ratio 3 : 1 was used. When given orally either glutamic acid tablets 0·5 or a solution of monosodium glutamate was given in divided doses throughout the twenty four hours.



Plasma-cystine levels in two patients under treatment with glutamic acid.

most notable finding being the very high plasma thionine level. In the 2 cases of acute hepatic necrosis raised levels and disturbed pattern of the amino-acids the blood were more striking, here again the raised blood methionine level was the outstanding finding tamine was also detected in the plasma of one of the 3 patients. In 1 of these cases the cerebrospinal fluid (C.S.F.) showed very high levels of glutamine thionine and an unidentified ninhydrin colour reactor, sibly γ-aminobutyric acid Excess of tyrosine, phenyl nine, glutamic acid, and methionine sulphoxide was so detected.

The C.S.F. glutamine level has been studied in more tail by the method of Whitehead and Whittaker (1955) 15 healthy people it ranged from 6 to 16 mg r 100 ml (mean 10 mg per 100 ml.) A patient with rrhosis but not in coma had a C.S.F. glutamine level of 7 mg per 100 ml.; and another, who later became matose, 27 mg per 100 ml Of 3 patients studied while coma 1 had a C.S.F. glutamine level of 40 mg per 100 l. on oral glutamic acid and 41 mg per 100 ml. after was discontinued; another had 41 5 mg per 100 ml. fore treatment and 44 5 mg per 100 ml while on travenous glutamate and the 3rd had 45 mg per 0 ml. These results confirm the chromatographic ndings of a very high C.S.F. glutamine level in hepatic ma but suggest that glutamic acid therapy does not se this level still further

The metabolism of cystine and cysteine has been studied y polarography The plasma-cystine level is often ced in severe chronic liver disease (Walshe and Senior 55). In view of Christensen's (1949) finding that rge doses of oral glutamic acid depress the level of other sma-amino-acids in dogs the plasma cystine levels re studied in 2 patients, and the results (see figure) gest that the plasma-cystine level may be depressed y large doses of glutamic acid The normal plasma stine level estimated by this method is 6–14 µg per 0 ml. with a mean of 10 64 µg per 100 ml (Dent et al 54) and the figure shows that this range was much ceeded in both cases studied

BLE I—BLOOD LEVELS OF KETO ACIDS IN HEALTHY PEOPLE AND PATIENTS WITH CHRONIC LIVER DISEASE

—	α Keto glutaric acid (µg per 100 g)		Pyruvic acid (µg per 100 g)		Aceto-acetic acid (µg per 100 g)	
	Range	Mean	Range	Mean	Range	Mean
11 healthy people	86–302	143	160–390	230	91–300	161
cirrhotics	147–187	161	270–312	317	141–367	238

Metabolism of Keto-acids

Disturbed metabolism of keto acids has been described in patients with liver disease (Amatuzio and Nesbitt 1950, Seligson et al 1952, Amatuzio et al. 1952, Smith et al 1953) α Ketoglutaric acid links the metabolism of amino acids with that of carbohydrates: glutamic acid ⇄ α ketoglutaric acid + ammonia (Weil Malherbe 1936); either disturbances of intermediary carbohydrate metabolism or a failure of the ammonia binding action of glutamic acid might be reflected by a rise in the concentration of this keto acid

By the method of El Hawary and Thompson (1953) the levels of α ketoglutaric acid, pyruvic acid, and aceto acetic acid were determined in healthy people, in patients with chronic liver disease, and in patients in hepatic coma The results for the healthy people and the patients with chronic liver disease are given in table I It can be seen that whereas the average values for the patients with liver damage are higher than those of the healthy people, they remain within the range of normal variation The normal values given here agree well with those published by El Hawary and Thompson (1953) so far as the ketoglutarate and aceto acetate are concerned, but those for pyruvate are somewhat lower possibly owing to decomposition of this unstable compound during the lengthy process of extraction Oral doses of glutamic acid 10 g did not alter the blood ketoglutarate level in healthy people, nor did a rapid intravenous infusion of sodium glutamate 12 g much affect this fasting plasma ketoglutarate 106 µg per 100 g; after intravenous glutamate 125 µg per 100 g There was also no significant change in the levels of the other keto-acids This rapid glutamate infusion was much better tolerated by healthy persons than by patients with severe liver disease who may retch and salivate if the infusion is given too fast

TABLE II—BLOOD LEVELS OF KETO-ACIDS IN HEPATIC COMA IN A PATIENT WITH POST HEPATITIS CIRRHOSIS

Specimen no.	α Keto glutarate (µg per 100 g)	Pyruvate (µg per 100 g)	Aceto acetate (µg per 100 g)	Therapy and C.N.S. signs
1	300	583	406	No therapy precomatose state
2	314	720	635	8 hr after oral glutamate normal C.N.S.
3	364	350	445	2 hr after glutamate normal C.N.S.
4	437	537	314	No therapy terminal coma

TABLE III—BLOOD LEVELS OF KETO-ACIDS IN HEPATIC COMA IN A PATIENT WITH MASSIVE HEPATIC NECROSIS

Specimen no	α Keto-glutarate (µg per 100 g)	Pyruvate (µg per 100 g)	Aceto-acetate (µg per 100 g)	Therapy and C.N.S. signs
1	195	358	322	No therapy in coma
2	231	485	368	On I.V. glutamate and glucose coma
3	281	870	2420	On I.V. glucose only terminal coma

2 patients in hepatic coma were studied The 1st (case 4) had post hepatitis cirrhosis (table II)

The 2nd patient studied in hepatic coma was case 6 with massive hepatic necrosis (table III)

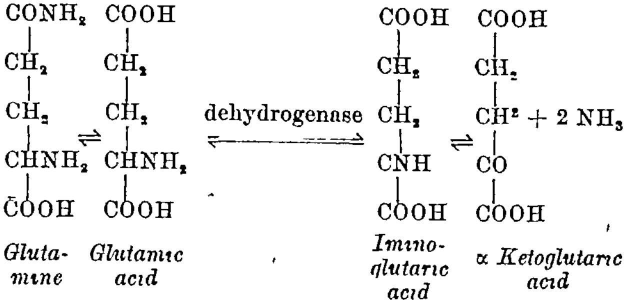
A single specimen of blood was obtained from a patient who had been in coma for more than a week after thrombosis of his portal and collateral veins; he was receiving 10% glucose intravenously at the time The blood ketoglutarate level was 338 µg per 100 ml., the pyruvate 1020 µg per 100 ml. and the aceto-acetate 455 µg per 100 ml †

---

† Markees (19) suggests that the spot identified by El Hawary and Thompson (1953) as aceto-acetate may in fact be " pyruvate spot II " resulting from an isomer of pyruvic acid

Discussion

The present cases further support the theory that large doses of glutamic acid are sometimes of value in the treatment of coma in patients with hepatic cirrhosis The rôle of glutamic acid in the metabolism of the brain has been reviewed and discussed by Weil Malherbe (1952) Enzyme systems are present in the brain for the amidation, transamination, decarboxylation, and oxidation of glutamic acid In the ammonia binding mechanism glutamic acid probably enters the following reactions



$$\underset{\text{Glutamine}}{\begin{array}{c}CONH_2\\|\\CH_2\\|\\CH_2\\|\\CHNH_2\\|\\COOH\end{array}} \rightleftharpoons \underset{\text{Glutamic acid}}{\begin{array}{c}COOH\\|\\CH_2\\|\\CH_2\\|\\CHNH_2\\|\\COOH\end{array}} \xrightleftharpoons{\text{dehydrogenase}} \underset{\text{Imino-glutaric acid}}{\begin{array}{c}COOH\\|\\CH_2\\|\\CH_2\\|\\CNH\\|\\COOH\end{array}} \rightleftharpoons \underset{\alpha\text{ Ketoglutaric acid}}{\begin{array}{c}COOH\\|\\CH_2\\|\\CH_2\\|\\CO\\|\\COOH\end{array}} + 2\,NH_3$$

Thus an excess of intracellular ammonia will lead to a shift to the left in these reactions, with a consequent reduction in the supply of 4 carbon acids for the citric acid cycle This in turn would give rise to a switch in pyruvate metabolism to the formation of aceto acetate The necessary supply of ketoglutarate could be maintained by pyruvate and oxalo acetate accepting amino groups from glutamic acid, thereby permitting normal functions of both the Krebs cycle and the ammonia binding mechanism The high concentration of glutamic-acid decarboxylase in the brain probably mediates the reaction glutamic acid ⇌ α aminobutyric acid + CO_2 The escape of the resultant CO_2 would lead to a reduction in acidity and the freeing of fixed base Finally, glutamic acid carries the K^+ ion into the cell, probably as the preferential cation associated with the glutamic-acid anion (Terner et al 1950)

All the more recent workers in this field have assumed, without further evidence, that the importance of glutamic acid in hepatic coma lies in its key rôle in the ammonia-binding mechanism Riddell and McDermott (1954) show that, in patients in hepatic coma, the blood-"ammonia" level fell after the intravenous infusion of glutamic acid, a temporary fall was observed by Sherlock et al (1954), and the diagrams of Singh et al (1954) also appear to illustrate this, although these workers interpret their results otherwise The present biochemical studies throw no further light on the underlying metabolic disturbances No consistent changes were found in the blood levels of the amino acids, although the blood-methionine level was often raised The metabolism of keto acids also appeared to be disturbed, but intravenous glutamic acid did not much raise the blood-ketoglutarate levels, nor did the blood level of aceto-acetate rise consistently as might have been expected if the supply of 4-carbon acids for the citric-acid cycle had been reduced seriously by a disturbance of the ketoglutarate ⇌ iminoglutarate equilibrium in favour of the latter (cf Weil-Malherbe 1952) Moreover other factors, such as starvation and glucose loading, must have played a part in the high blood-levels of aceto-acetate and pyruvate which were found on occasions Bessman and Bessman (1954) believe that the toxic action of ammonia is the removal of ketoglutarate from the Krebs cycle, but they did not allow for the replacement from glutamic acid by the transamination reaction described by Weil Malherbe (1952)

In all the present cases where it was estimated the C S F-glutamine level was raised to approximately the intracellular level of glutamine but was not raised further by glutamic acid therapy, a finding which has also been reported by Whitehead and Whittaker (1955) This could be due either to a leakage of glutamine from the damaged cortical neurones or a compensatory mechanism to remove excess ammonia bound by the intracellular enzyme systems Such an enzyme system might then become exhausted, in the presence of severe liver disease, or blocked by some glutamic-acid antimetabolite (Walshe 1951), and failure to detect consistent changes in the blood level of either "ammonia" or keto acids would not eliminate the possibility that a deranged ammonia metabolism is important in the genesis of hepatic coma The undoubted fact that both oral ammonium salts and a high protein diet given to patients with severe liver damage can produce a syndrome closely mimicking hepatic coma further supports the theory that disturbed ammonia metabolism is in some way connected with the naturally occurring syndrome, but does not mean that it is the only cause of hepatic coma Indeed, Seegmiller et al (1954) have achieved very high blood "ammonia" levels (1 8 mg per 100 ml) without producing abnormal neurological signs, and Benitez et al (1954) note that the direct application of ammonium salts to the cortex did not give rise to altered cortical electrical activity, but they did find that the brain ammonia-level rose in fluoro acetate poisoning without a corresponding rise in the blood ammonia level Under the experimental conditions the cerebral ammonia was not readily converted to glutamine It has also been shown that the brain-ammonia level rises after electrically and chemically induced convulsions and in anoxia (Waelsch 1951) In severe hepatic disease, therefore, when the ammonia binding mechanism remains intact, a relatively high blood ammonia level could, at least in theory, be well tolerated, whereas in cases where some inhibiting factor was present a normal or only slightly raised blood ammonia level might exist coincidentally with a toxic level in the cortical neurones This could account for the conflicting evidence reported by many workers on the correlation of neurological signs with the blood ammonia levels It should perhaps be mentioned at this stage that the assumption that ammonia, in the concentrations reported, has a direct toxic action on th brain is not entirely supported by the available exper mental evidence, for, apart from the work of Benit et al (1954), Terner et al (1950) found that, althoug 0 005 *M* ammonia, a concentration many times great than that found in hepatic coma, caused a fall in th tissue potassium level it did not inhibit the uptake oxygen by brain slices Similarly, it has been reporte by Edson (1935) that the metabolism of brain slices in glucose medium is not inhibited by a 0 01 *M* concentration of NH_4Cl, a concentration which will reduce th respiration of the liver by 20%

It is not generally realised that the administration o methionine to patients with advanced liver disease ma be followed by coma This was first noted by Watso (1949), and more recently by Sherlock et al (1954 studying the toxic effects of nitrogenous compound in patients with portal hypertension The possibl mechanisms are discussed by Challenger and Walshe (1955a and b)

In an organ mediating as many complex metabolic pathways as does the liver it is unlikely that any single cause underlies all cases of hepatic coma In acute hepatic necrosis there is, in addition to a disturbed or destroyed hepatic function, the element of intoxication from the rapid necrosis and autolysis of hepatic parenchymal cells In hepatic cirrhosis two factors need consideration (1) in many cases there is a progressive loss of liver cells together with impaired function of the survivors, which must inevitably lead to a stage at which the liver can no longer support life, in chronic alcoholics, moreover, the picture is further complicated by damage to the nervous system by multiple enzyme deficiencies, and (?) in cases with chronic liver damage some precipitating factor, such as hæmorrhage, will precede the onset of coma, and it is in these cases only that therapy can hope to produce a temporary recovery, it is in this group that glutamic acid may prove of value.

Summary and Conclusions

The results obtained with intravenous sodium (or sodium and potassium) glutamate in the treatment of hepatic coma are reported 5 patients with chronic liver disease were each treated for one or more episodes of coma: 3 responded favourably but 1 died shortly after of massive gastro intestinal bleeding and 2 responded only partially and died later of progressive hepatic failure

2 cases of massive hepatic necrosis showed no response to treatment.

The rôle of ammonia in the pathogenesis of hepatic coma is discussed. The integrity of the intracellular ammonia binding mechanisms is probably more important than the plasma-ammonia level A high blood ammonia level may be well tolerated in those cases of liver disease in which the ammonia binding mechanism remains intact, and disturbances of this function may lead to the development of coma even before the blood ammonia level rises.

Certain disturbances of sulphur metabolism in hepatic coma are described. Large oral doses of methionine may precipitate coma Some possible toxic actions of methionine and closely allied compounds, referred to by Challenger and Walshe (1955b) are described

There is probably no single cause of hepatic coma common to all cases, and it would probably be more accurate to refer to 'the hepatic comas.

I wish to thank the Royal Society for a full time research grant, the Stothert research fellowship Prof M. L. Rosenheim for his advice and encouragement and for his and Dr. J D Nabarro s permission to study their cases.

FŒTOR HEPATICUS

F CHALLENGER
D.Sc. Birm. F.R.I C
EMERITUS PROFESSOR OF ORGANIC CHEMISTRY IN THE UNIVERSITY OF LEEDS

J M. WALSHE
M.A M.B Camb M R C.P

From the Department of Colour Chemistry University of Leeds and the Medical Unit University College Hospital London

THE breath of patients with severe parenchymal liver disease often has a characteristic odour, fœtor hepaticus, which has been described as a musty smell (Schiff 1946) 'the smell of a freshly opened corpse" (Himsworth 1947), and 'a mixture of rotten eggs and garlic' (Davidson 1949) The smell may be only just detectable or so strong as to fill the room and has been considered to be due to indol or to an amine (Lichtman 1949)

Attempts to isolate from the breath the compound producing the fœtor have failed because of the very small quantities involved and the difficulty of getting a seriously ill patient to breathe against the resistance of a collecting system From the smell Davidson believed it to be a mercaptan, possibly derived from methionine or from cystine but not necessarily dependent on methionine therapy

In patients with a strong oral fœtor a very similar smell may be present in the urine Butt and Mason (1954) believed that the compound producing fœtor hepaticus was also present in normal urine and from 75 gallons of normal urine they isolated 6 mg of a compound which they believed to be a cyclic amine with nitrogen in the ring This was lost during recrystallisation and a further extraction of 100 gallons of normal urine gave no significant yield

We have studied the urine of a patient with massive hepatic necrosis and a strong fœtor in her breath and urine.

Case-report

A housewife aged 45 was admitted to University College Hospital with jaundice and in light coma. Her illness had started six weeks previously (in December, 1953) with anorexia, diarrhœa, and nausea; after a few days she became jaundiced but did not take to her bed and after a short illness she appeared to recover A month later jaundice returned this time with severe vomiting and prostration. She was admitted in February 1954 to another hospital and treated with aureomycin for infective hepatitis; but her condition continued to deteriorate fœtor hepaticus was noted and she became delirious and lapsed into coma with extensor plantar responses and ankle clonus. At this stage she was transferred to University College Hospital. Her course was progressively downhill and she died nine days later despite treatment with 25% glucose intravenously, careful control of fluid and electrolyte balance and intravenous sodium glutamate No amino acid supplements were given. During this time her urine had a strong fœtor similar to that in the breath but rather more offensive; this was present as soon as the urine was passed and was not due to infection or to decomposition on standing Paper-chromatographic study of the plasma showed a moderate generalised increase of all amino-acids commonly present and a great increase of methionine

Necropsy (Dr R A. B Drury) showed extensive necrosis of the liver which weighed only 840 g this reduction being due to almost complete destruction of the parenchymal cells

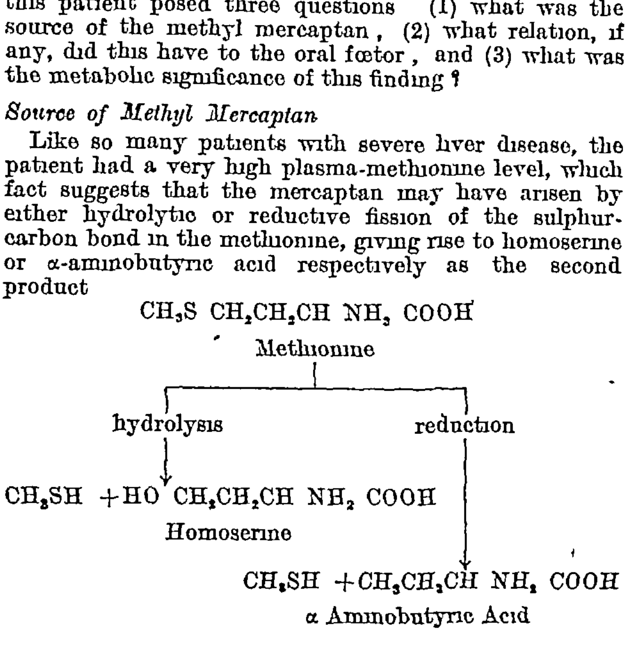
Examination of urine—The smell of the urine suggested that the compound responsible was either an alkyl mercaptan $C_nH_{2n+1}SH$ an alkyl sulphide $(C_nH_{2n+1})_2S$ or a dialkyl disulphide $C_nH_{2n+1}S\cdot S\cdot C_nH_{2n+1}$ or possibly all three We tried to isolate the responsible compound by bubbling a slow stream of nitrogen through 5 or 6 litres of urine next through dilute sulphuric acid (to remove ammonia) next through dilute mercuric cyanide and next through dilute mercuric chloride—a method evolved by Challenger and Rawlings (1937) and Blackburn and Challenger (1938) Details of the experimental procedure and the evidence for th chemical identification of the compounds isolated from the urine of this patient are described elsewhere (Challenger and Walshe 1955) The evidence obtained by this procedure showed that the urine contained methyl mercaptan (CH_3SH) as the principal compound producing the smell, and a smaller amount of dimethyl disulphide ($CH_3S\ SCH_3$), which may have resulted from oxidation of the methyl mercaptan after the urine was passed, there was no evidence for the presence of dimethyl sulphide in the urine

Discussion

The finding of methyl mercaptan, and probably dimethyl disulphide in smaller amounts, in the urine of this patient posed three questions (1) what was the source of the methyl mercaptan, (2) what relation, if any, did this have to the oral fœtor, and (3) what was the metabolic significance of this finding ?

Source of Methyl Mercaptan

Like so many patients with severe liver disease, the patient had a very high plasma-methionine level, which fact suggests that the mercaptan may have arisen by either hydrolytic or reductive fission of the sulphur-carbon bond in the methionine, giving rise to homoserine or α-aminobutyric acid respectively as the second product



$CH_3S\ CH_2CH_2CH\ NH_2\ COOH$
Methionine
hydrolysis
reduction
$CH_3SH\ +HO\ CH_2CH_2CH\ NH_2\ COOH$
Homoserine
$CH_3SH\ +CH_3CH_2CH\ NH_2\ COOH$
α Aminobutyric Acid

Such a fission, with the liberation of methyl mercaptan from methionine and S methylcysteine, is brought about by the mould *Scopulariopsis brevicaulis* (Challenger and Charlton 1947) The enzyme thionase occurring in liver (Binkley 1950), liberates methyl mercaptan from S methyl cysteine, $CH_3\ S\ CH_2\ CH\ NH_2\ COOH$ Its behaviour with methionine is not recorded Canellakis and Tarver (1953) report the formation of methyl mercaptan from methionine by rat-liver mitochondria

Normally the fate of methionine in the body, apart from being incorporated into protein, is to act as a source of cysteine and of labile methyl groups for the biological synthesis of choline, adrenaline, creatine, carnosine, and N-methyl-nicotinamide Probably many of these transmethylations occur in the liver and in cases of severe hepatic disease may be inhibited, with a consequent accumulation of methionine in the plasma, as happened in this patient Fission of the sulphur carbon link, with the formation of methyl mercaptan, may then be used as an alternative pathway to deal with the excess of methionine Evidence for this fission has also been obtained by Dent (1947), who found in healthy people and, especially, in a case of the Fanconi syndrome with hepatic cirrhosis an increased excretion of α-amino-butyric acid after the administration of methionine, " as if direct desulphurisation had taken place "

Relation to Oral Fœtor

In considering the relation of the methyl mercaptan in the urine to the oral fœtor it should be pointed out that this compound has a more offensive smell than is commonly associated with classical fœtor hepaticus Moreover, methyl mercaptan is relatively soluble, and the urine would be the natural route of its excretion However, dimethyl disulphide and methyl sulphide have an odour very like the sweetish oral fœtor Since the smell of these compounds can be detected in dilution of 10^{-7}, it can easily be realised how difficult would be to identify chemically such substances in th breath Moreover, if methyl mercaptan is present in th body, it is more than likely that at least a small proportion would be either methylated to dimethyl sulphid or oxidised to the disulphide The odour of garlic, whic has been likened to that of fœtor hepaticus, is due t diallyl disulphide ($(CH_2\ CH\ CH_2\ S-)_2$ Probably th smell of fœtor hepaticus is due to a mixture of dimethy disulphide, dimethyl sulphide, and methyl mercaptan possibly the proportions of each may vary in differen patients, explaining the differences in smell described b various observers

Metabolic Significance

Finally, are these findings of metabolic significance o of purely academic interest ? The finding of thiol group in the urine appears most surprising in view of the spee with which cysteine is oxidised to cystine in the blood It is perhaps a comparable finding to that of Walshe an Senior (1955) that patients with severe liver diseas cannot clear the blood of cysteine as fast as can health people The failure to convert the mercaptan to detectable amounts of dimethyl sulphide also points to seve impairment of methylation in the liver

The inability of the patient to metabolise methioni at the normal rate may also be of significance Ear et al (1942) showed that, when more than 6% of methionine is added to a low protein diet rats develop liv atrophy with a high mortality in one week Hepat coma has also developed in patients with severe liv damage when methionine has been given (Watson 194 Sherlock et al 1954) This action of methionine has bee attributed to the amino group, but the evidence is n entirely convincing Methionine itself is not necessari toxic, but perhaps some related intermediate metaboli may also accumulate Methionine sulphoxide is glutamic acid antimetabolite to *Lactobacillus arabino* (Waelsch et al 1946, Borek et al 1946) and so, theoretically, could inhibit the utilisation of glutamic acid in th brain Methionine sulphoximine, the toxic factor agenised flour, produces fits in dogs, an action that may reversed by glutamine (Bentley et al 1950, Heathcote an Pace 1950), a compound which it resembles structurall Is methyl mercaptan itself toxic ? We have been unab to find any evidence on this in published reports, b analogy with two closely related compounds suggests th it may well be so, there is clearly a close structural a chemical relationship between methyl mercaptan (CH_3SH and hydrogen sulphide (HSH) and methyl alcoh (CH_3OH) Hydrogen sulphide, in comparable concentrations, is as toxic as cyanide and interferes with th cytochrome system, and methyl alcohol is, as is we known, poisonous to the central nervous system Robert and Eckstein (1944) have found that dimethyl disulphi is toxic to rats in a dose of 90 mg per kg of body weig and then appears to yield methyl mercaptan. There no information about dimethyl sulphide, but this compound is a thio ether and so may well be toxic also

Summary

Methyl mercaptan was isolated from the urine of patient with massive hepatic necrosis, some dimeth disulphide was probably also present

It might be expected that, in the body, meth mercaptan would be either oxidised to dimethyl disulphide or methylated to dimethyl sulphide

We believe that fœtor hepaticus is caused by the elimination of one or more of these compounds in the breath

Little is known of the pharmacology of these compounds, but by analogy with closely related compounds they may well be toxic

We wish to thank Prof M L Rosenheim for permission to study this patient F C thanks Prof W Bradley for the hospitality of his department and J M W is indebted to the Royal Society for a whole time grant the Stothert research fellowship

THE TREATMENT OF ECLAMPSIA (IMMINENT OR ACTUAL) BY CONTINUOUS CONDUCTION ANALGESIA

R Bryce-Smith
M.A B.M. Oxfd., F.F.A.R.C.S
ASSISTANT NUFFIELD DEPARTMENT OF ANÆSTHETICS, OXFORD

E O Williams
M.A., B.M Oxfd, F.R.C.S M.R.C.O.G
CONSULTANT OBSTETRICIAN AND GYNÆCOLOGIST GUILDFORD SURREY

In 1947 a method of treating eclampsia by continuous conduction block was described by Hingson et al This followed the observations of Sarnoff and Farr (1944) that a single-dose spinal block was beneficial in hypertensive heart failure, and the realisation that spinal or extradural analgesia offered many advantages in the relief of pain during labour for patients handicapped by either cardiac or respiratory disease (Pitkin and McCormack 1928 Cosgrove et al 1937 Hingson and Edwards 1943)

At different times spinal analgesia has been strongly advocated for obstetric operations in toxæmic and eclamptic patients, but we believe that it was used therapeutically for the first time in 1928 (Paramore 1928) The introduction of methods which allowed conduction blocks to be maintained for long periods (Lemmon 1940 Hingson and Edwards 1942) greatly added to the practical value of this approach in the management of eclampsia. In this way it is possible to produce a controllable fall in blood pressure for any required length of time thus reducing the load on an embarrassed heart and avoiding the dangers of fœtal sedation

The first case to be treated thus in the United Kingdom was described by Bryce Smith et al (1949) Since then we have treated six more cases and in the light of this experience we have some further observations to make

Case reports

Case 1 —A primigravida aged 21 had a normal antenatal history until the 31st week, after which the blood pressure rose steadily œdema of the legs and albuminuria appeared and she was delivered of a stillborn child at the 35th week. After this she was admitted to this hospital as an emergency with a blood pressure of 170/100 mm Hg generalised œdema uræmia, anuria headache and disturbance of vision For the next twenty four hours during which she was sedated heavily the blood pressure continued to rise and the signs of cerebral irritation increased

A continuous caudal block was started but had little effect on the blood pressure despite apparently satisfactory high levels of analgesia (fig 1) The patient said she felt more comfortable but after twenty four hours she was becoming unmanageable and it was feared that she would pass into acute heart failure

A continuous spinal block was therefore established and her general condition much improved; the blood pressure was controlled (fig 2) and the cerebral symptoms vanished. During the ensuing thirty six hours there was a steady increase in urinary output (fig 3) with a corresponding reduction of œdema. The block was maintained for five and a half days, and only minimal sedation was necessary to maintain the required restful state The patient made such good progress that the catheter was removed but four days later finding restrictions of her activity irksome she got out of bed while unattended for a moment, collapsed and died of acute heart-failure

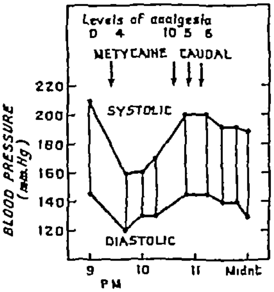

Fig 1—Case 1: Apart from an initial fall following the establishment of the caudal block the blood-pressure remained high in spite of adequate levels of analgesia.

Case 2 —A primigravida, aged 34 was admitted to hospital as an emergency having had four eclamptic convulsions at home Her normal weight was 20 st. and she was not aware that she was pregnant although her uterus was enlarged to the size corresponding to a pregnancy of 36 weeks. At this time her weight was estimated at 26 st. She was breathless delirious and uncoöperative Her blood pressure was 280/220 mm. Hg and she had oliguria, albuminuria, and gross œdema. Heavy doses of sedatives administered for eighteen hours did not alter this picture

A continuous lumbar extradural block was instituted For four hours there appeared to be some reduction in the systolic blood pressure with a gradually falling pulse-rate Subsequently the blood pressure was not lowered effectively although an increased volume of solution was injected into the extradural space; and there was some doubt about whether the catheter was correctly situated

A continuous spinal block was therefore substituted which brought the blood pressure under immediate control (fig 4) with satisfactory improvement in the patient's general condition. The spinal block was maintained for three days, during which no sedatives were necessary and within twenty four hours the output of urine had returned to normal (fig 3)

Progress —The blood pressure tended to settle at 140/90 mm. Hg presumably the patient's normal level, and no attempt was made to reduce it further The patient went into spontaneous labour eighteen hours after the start of the spinal block and was delivered of a stillborn fœtus It was not known whether the fœtus was alive when the patient was admitted because it was impossible to detect the fœtal

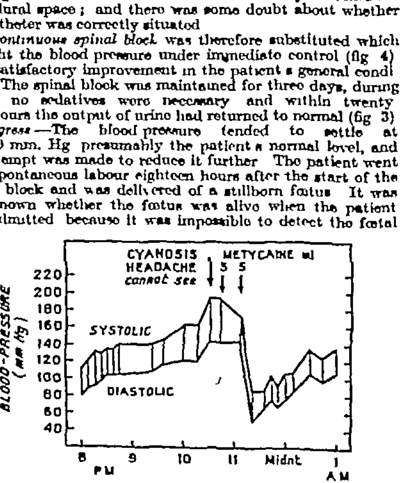

Fig 2—Case 1: dramatic effect of spinal analgesia on blood-pressure

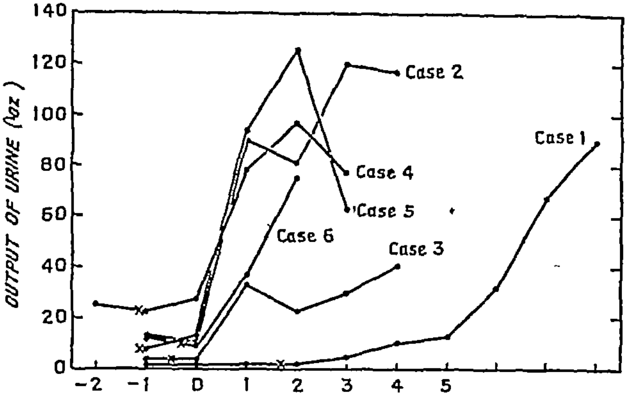

Fig 3—Daily urinary outputs of the six cases described : X, indicates time at which relevant blocks were established, and D the day of delivery Cases 1 and 3 suffered severe permanent renal damage, which probably accounts for their failure to conform to the pattern of post delivery diuresis seen in the other cases.

heart in the presence of such gross obesity When the catheter was to be removed from the subarachnoid space, a routine sample of cerebrospinal fluid (C S F) sent for examination showed infection with *Pseudomonas pyocyanea* This complication resulted from the incontinence of the patient and from the difficulties of nursing a paralysed woman of this weight The infection was overcome with massive intrathecal injections of streptomycin. There were no clinical signs of meningitis, and the patient made a full recovery with no signs of renal or cardiac damage

Case 3 —A primigravida, aged 21, who had received inadequate antenatal supervision, was admitted to hospital as an emergency at 28 weeks, having had three eclamptic convulsions at home On admission she was restless and uncoöperative, with a blood pressure of 190/150 mm Hg, albuminuria, and slight œdema Sedatives had little effect on the blood-pressure

A lumbar extradural block was instituted. The patient went into spontaneous labour and the blood pressure was efficiently controlled for about four hours, while labour progressed without disturbing the patient Thereafter, although increasing volumes of local analgesic solution were injected and had some effect, it became increasingly difficult to lower the blood pressure (fig 7) Restlessness increased, and it was discovered that the 'Polythene' tubing had broken at the skin margin. Rather than re-establish an extradural or spinal block through a potentially infected extradural space we reluctantly reverted to heavy sedation. Since the initial treatment had been ineffective, we were not surprised that this had little effect on the blood pressure, and the patient caused anxiety until she was delivered of a stillborn fœtus fourteen hours later The distal fragment of the polythene catheter was not removed at the time, and an attempt to locate it three weeks later was unsuccessful When seen a year later, the patient had not suffered on account of this, but she exhibited permanent and grave hypertensive damage to her kidneys and heart This case did not show a characteristic diuresis after delivery, and this is probably related to her permanent renal damage (fig 3)

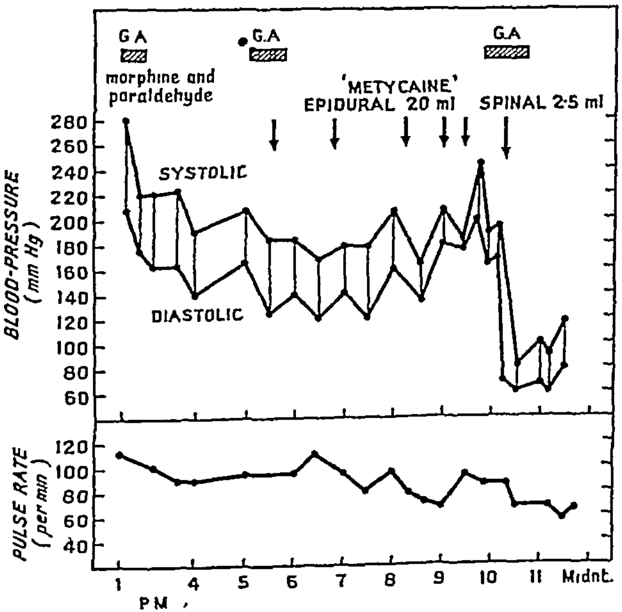

Fig 4—Case 2, showing effects of lumbar extradural and spinal blocks : G.A., general anæsthesia.

Case 4 —A primigravida, aged 19, was a booked case with a normal antenatal history until the 33rd week, when she had a raised blood pressure, albuminuria, and œdema of the face On admission to hospital next day the blood pressure had risen to 180/130 mm Hg and there was massive albuminuria Heavy sedation maintained for sixteen hours had no effect on the blood pressure

A continuous lumbar extradural block was instituted, and the patient was delivered spontaneously forty two hours later of a living baby weighing 4 lb During the period of continuous extradural block it was found that labour appeared to be retarded when the level of the block was raised to control the blood pressure adequately After thirty hours it became necessary to increase the volume of the local analgesic solution injected and to make the injections more frequently Thus at the beginning of the treatment 15 ml of 1% lignocaine was effective, but at the time of delivery 50–60 ml of solution was required to achieve the same effect (fig 8) The urinary output returned to normal rapidly (fig 3), and the patient made a satisfactory recovery

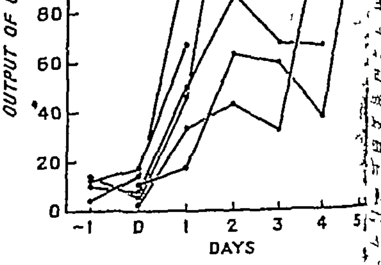

Fig 5—Daily urinary outputs of six eclam patients treated by heavy sedation.

Case 5 —A primigravida, aged 21, had a normal antenatal history until the 28th week, when the blood-pressure started to rise and œdema and albuminuria appeared At 36 weeks the patient was admitted to hospital as an emergen with a blood pressure of 200/140 mm Hg, generalised œdem drowsiness, and severe oliguria Sedation with morphine a paraldehyde maintained for six hours had little effect on t blood pressure

A continuous lumbar extradural block was instituted Uteri contractions were noticed at this time but ceased when t level of analgesia rose above T9 To control the blood pressu a higher level was required, and this presented difficulty witho interfering with labour After about twelve hours it beca necessary to increase the volume of solution injected a to make the injections more frequently Minimal sedati was required, and after twenty four hours the patient w delivered by forceps of a live baby Although analgesia w adequate for delivery, an acute hypertensive crisis develop immediately afterwards, and this could not be controlled b the block It became necessary to reinstitute heavy sedatio and within one or two hours the blood pressure had settled a the patient made an uninterrupted recovery with a satisfacto diuresis (fig 3) In retrospect we believe that the *conductio* block was started before sedation had been given a fair tri

Thus this case differs from the five others in whic sedation was fully exploited, and even then did not lowe the blood pressure A further point in this patient's history is worthy of interest when a rapid injection wa made through the extradural catheter, the patien complained of severe headache, persisting for about on minute, when the injection was made slowly this di not happen The ætiology of this phenomenon is discussed below

Case 6 —A multigravida aged 27 was admitted to hospital from the antenatal clinic at the 35th week with a raised blood pressure and albuminuria. For the next three days the blood-pressure continued to rise until it reached 220/140 mm. Hg despite treatment with diamorphine hydrochloride 'Sodium amytal' 'Serpasil,' and, later morphine and paraldehyde.

A lumbar extradural block was established under general anæsthesia, and the membranes were ruptured No further sedatives were given and the blood pressure was immediately controlled with extradural injections of 1% lignocaine and for several hours remained constant at 110/80 mm Hg—the patient's normal level. Strong uterine contractions were occurring regularly but for ten hours there was clinically little evidence of progress It then became necessary to give the extradural injections at shorter intervals, but despite this the blood pressure could not be maintained as steadily as before This led us to believe that labour was now progressing rapidly and she was delivered spontaneously three hours later of a living female child weighing 5½ lb

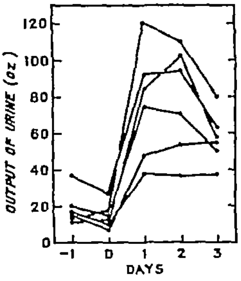

Fig 6—Daily urinary outputs of six healthy obstetric patients.

Sedation

To avoid repetition details of sedation have not been included in the case reports The routine adopted in all cases is the administration of heavy doses of sedatives to lower the blood pressure and to control convulsions. Where necessary a general anæsthetic may be given also to assess the patient obstetrically Thus, as an extreme example case 2 received a general anæsthetic, followed by rectal paraldehyde 21 ml in olive oil, intramuscular paraldehyde 10 ml morphine 32 mg., and sodium amytal 300 mg within ninety minutes Although convulsions ceased and her respirations decreased to 6 per minute her blood pressure was not controlled. If, however a satisfactory reduction of blood pressure is achieved it can generally be maintained by giving intramuscular morphine 16 mg, and rectal paraldehyde 21 ml (in 170 ml of olive oil) alternately every four hours

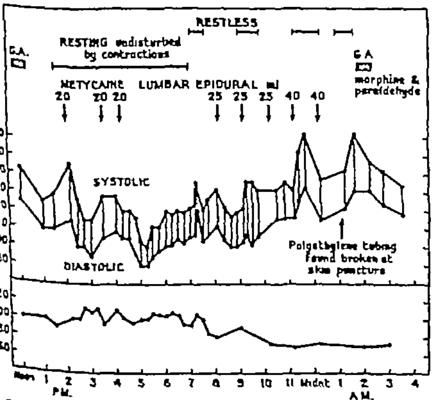

Fig. 7—Case 3 showing failure of what had been an effective extradural block owing to breakage of the polythene catheter: G.A., general anæsthesia.

Methods and Technique of Anæsthesia

In the six cases reported here, caudal, lumbar extradural and spinal approaches were used A length of plastic tubing was inserted through either a caudal or a Tuohy needle (Southworth et al. 1953) The site of puncture is sealed with paraffin gauze impregnated with penicillin powder, and the external part of the plastic tubing is fastened to the patient's back with a long length of adhesive strapping 2 inches wide The free end, to which a syringe remains attached can be either brought over the patient's shoulder and fixed to the chest or placed under a pillow

Since conduction blocks of this type may need to be maintained for several days at a time the risk of infection is obvious, and the utmost care is needed to avoid contamination of the free end of the plastic catheter To ensure this a syringe attached to the free end of the tubing provides, we believe, the most effective seal, but a fresh sterile syringe must be used for each injection When a continuous spinal block is in progress the pressure of C.S.F may force back the plunger of the syringe allowing it to become contaminated This can be avoided by strapping the plunger to the barrel of the syringe It is advisable to take routine samples of C.S.F so that if infection is introduced it may be recognised immediately and appropriate treatment instituted

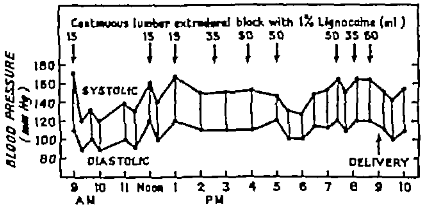

Fig 8—Case 4 showing control of the blood-pressure; it was necessary to increase progressively the volume of local analgesic solution injected into the extradural space and to make these injections at shorter intervals.

Since it is often difficult to achieve an adequate level of analgesia with a caudal block we believe that this approach is the least useful in the management of eclampsia Usually, a continuous caudal block used for delivery in normal obstetrics has little effect on the blood pressure (Lull and Hingson 1948) and this was so in case 1

A lumbar extradural block usually provides adequate levels of analgesia and efficient control of the blood pressure for limited periods. However in all the cases in which the method was used it was found that, with the passage of time, increasing volumes of solution were needed to obtain the desired result and that as the time for delivery approached the injections had to be given more frequently Also on some occasions it became impossible to provide a sufficient fall in blood pressure There is no doubt that a spinal block provides a far more efficient and certain method of controlling the blood pressure, but this technique carries with it the risk of meningitis.

Case 1 shows that violent swings of blood pressure can lead to heart failure whose warning signs are a falling pulse pressure and a rising pulse-rate (fig 9) If the blood pressure and pulse rate are charted graphically these signs are seen readily This method of recording also demonstrates the basic blood pressure level of each case, and no advantage is gained by lowering the blood pressure further (cases 2 and 6)

Before any of the blocks under discussion are undertaken, certain safety measures should be to hand—oxygen, a means of inflating the lungs, transfusion apparatus, a tilting bed, and a vasopressor drug such as methylamphetamine hydrochloride ('Methedrine') A syringe containing thiopentone is advisable, too, in view of the remote possibility of convulsions due to rapid absorption of the drug used for producing local analgesia

The injection of solution into the extradural space undoubtedly influences the pressure of the C S F, and this fact has been used in treating postspinal headaches (Rice and Dabbs 1950). However, we are not aware of any method which will raise the pressure of the C S.F in a healthy person to such an extent that headaches result Case 5 is exceptional in that a rapid injection of solution into the extradural space caused a violent headache lasting about a minute A slow injection did not have this effect This time relationship coincides closely with the duration of peak C S F pressures when these are raised by injection into the subarachnoid space (as during the induction of spinal analgesia) Experiments made by one of us (R B-S) showed that the intraspinal injection of 15 ml of light cinchocaine could raise a normal C S F pressure to about 650 mm H_2O, but the pressure fell rapidly to 150 mm H_2O within thirty seconds and then returned to the normal pre injection level much more slowly In these experiments the patients suffered no headaches, but it could be argued that in case 5 the C S F pressure was already raised by œdema of the brain

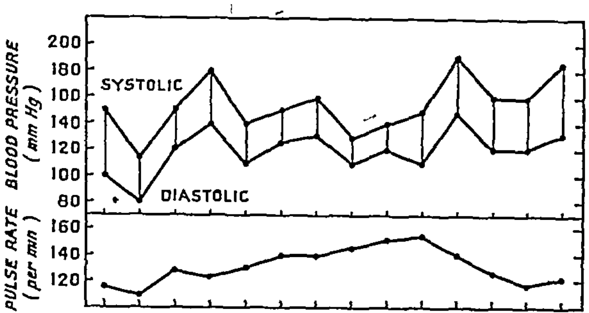

Fig 9—Case 1: In an effort to promote diuresis the blood pressure was made to "swing" During the period between 5 p m and 9 p m the pulse-pressure fell and the pulse-rate (indicated by the lowest line) rose, the patient tended to be slightly cyanosed, and her respiration became "bubbly" As the pulse-pressure increased, so the pulse-rate fell and the patient's general condition improved

Obstetric Problems

There seems to be little doubt that, once the blood pressure has been controlled by continuous conduction block, heavy sedation is unnecessary By controlling the blood-pressure it is possible to avoid eclamptic convulsions and the subjective symptoms of headache, disorientation, and blurred vision so commonly present in a hypertensive crisis

The avoidance of heavy sedation by using continuous conduction block offers the best chance of survival for the fœtus and tends to reduce the incidence of respiratory morbidity in the mother The comparison between the wide awake cooperative patient under conduction block and the comatose woman under heavy sedation, who, despite skilled nursing, is liable to develop pulmonary complications, is most striking The dangers in heavy sedation of balancing the claims of the fœtus against those of the mother, as the time of delivery approaches, can also be avoided Apart from its therapeutic value the block also serves as the anæsthetic for delivery, whether operative or spontaneous

In cases 4 and 5 there was evidence that the progress of labour was retarded by the block when it reached the level considered adequate for controlling the blood pressure It often requires fine judgment to choose the proper dosage which will provide a level of analgesia sufficient to control the blood pressure yet at the same time not interfere with the normal course of labour

We intend in future to maintain the block at the best level for controlling the blood-pressure and to use, when necessary, an oxytocin drip (1–5 units of oxytocin per 500 ml of 5% glucose solution according to individual response) to stimulate a normal rate of labour

Effect on Urinary Secretion

Hughes et al (1948) described dramatic responses i patients with oliguria and even anuria to continuou conduction blocks This was not seen in any of our case All, however, showed a striking diuresis followin delivery, which usually took place within twenty fou hours of establishing the block (fig 3) Daily urinar output charts of six eclamptic patients treated by heav sedation with morphine and paraldehyde (fig 5) and s healthy obstetric patients (fig 6) show a similar patter As might be expected, the daily output of the health patients was not usually so high as that of the eclampti patients, since excessive antenatal retention of fluid characteristic of the latter group

We have seen anuria from other causes respon favourably to block therapy, but in this series the post partum diuresis was related to the time of deliver an was uninfluenced by any therapeutic measures

Conclusions and Summary

Six cases of eclampsia treated by continuous conductio block are described Our present impression is that block by the caudal route is of little value The bloo pressure is controlled most effectively by continuo spinal analgesia, but this carries the risk of meningit A continuous lumbar extradural block is safer, and i twenty four hours will give almost as good results a spinal

Whichever method is chosen, there is a chance th labour will be retarded by a block which reaches t optimal level (varying from patient to patient) f controlling the blood pressure. In such instances, it suggested, rather than to lower the level of the block, pitocin drip should be established to stimulate norm uterine function

The improvement in the appearance of an eclampt patient treated with conduction analgesia is strikin and, since heavy sedation is unnecessary, matern morbidity is reduced and the fœtus offered better chan of survival

On these grounds a continuous conduction block i selected cases is preferable to treatment with sedatives but, since a postpartum diuresis can be expected t follow delivery in most cases, eclamptic oliguria by its does not necessarily provide a specific indication fo block therapy

At present we do not feel justified in suggesting th a conduction block be used in all cases of severe toxæmi but in desperate cases, such as we have described, bloc therapy has much to offer Nevertheless such treatmen presents a disadvantage, since it is necessary to provid constant supervision throughout the twenty four hour by an anæsthetist and an obstetrician, who must alwa be at hand

We are grateful to the nurses for their untiring help wit these cases, Sir Robert Macintosh for his valuable adv and assistance, and Mr J Stallworthy and Mr W Hawksworth, under whose care these patients were admitted to the United Oxford Hospitals, for their advice and permission to publish

FUTURE progress in the prevention and treatment of deformities will largely depend on increasing our knowledge of their ætiology Although the conclusions of this paper are tentative and incomplete, we feel that they are worth recording because they throw light on a difficult and important problem—the ætiology of scoliosis.

In some cases of scoliosis there are obvious skeletal abnormalities—e.g, hemivertebræ, fused ribs, and funnel chest These are cases of congenital scoliosis

In other cases the scoliosis develops after an attack of poliomyelitis—so-called paralytic scoliosis Even in these cases, however the exact mechanism of production of the deformity is uncertain (Steindler 1929 Lowman [illegible], Mayer 1936 Colonna and Vom Saal 1941) If it is merely a question of muscle imbalance which muscles are concerned ? Spinal or extraspinal ? If spinal are the stronger muscles on the convex or the concave side ? It has been suggested that fascial contracture (Bennett [illegible]52, Clark 1954) may be responsible or that there is a primary disturbance of vertebral growth even in paralytic cases

Next there is a relatively small group of cases in which the scoliosis is associated with a condition such as muscle dystrophy neurofibromatosis syringomyelia or hereditary ataxia

Finally there is the largest group of cases in which no definite cause can be found for the scoliosis—the 'idiopathic' group

The object of the present investigation was to assess the rôle of muscle imbalance in scoliosis Known cases of paralytic scoliosis were examined to find out which muscles were weak and what type of imbalance caused deformity Next some cases of idiopathic scoliosis were examined to discover whether occult muscle imbalance (undetectable clinically) played a part in causing some of these deformities The theory that many cases of idiopathic scoliosis are due to an undiagnosed attack of poliomyelitis is, of course an old one but hitherto it has been hard to find objective evidence in support of this theory We also examined cases of congenital scoliosis to act as controls.

Methods

It is relatively easy to assess the strength of limb muscles clinically but it is difficult to assess the strength of individual trunk muscles by ordinary clinical means. Jansen (1913) suggested that unequal diaphragmatic activity was a cause of scoliosis Therefore we had radiographs taken of both sides of the diaphragm in full inspiration and full expiration, and measured their excursion The other trunk muscles were assessed by electromyography

A two channel electromyograph was used to compare the activity of muscles on each side of the body Recordings were usually made with surface electrodes but in some cases needle electrodes were also used for the deep spinal muscles

The electromyograms were displayed side by side on a double beam oscilloscope and their amplitudes compared The amplitudes are directly related to the mechanical response of the muscles (Inman et al 1944 Loofbourrow 1948) they were expressed as submultiples of a full scale deflection arbitrarily defined as 5 units

The procedure adopted was as follows When the patient was comfortable on a couch the skin over the *muscles to be investigated was carefully cleaned and* massaged with an electrode jelly saturated with salt. The electrodes were next placed at equal distances apart on either side A standard distance could not be adopted because of the deformities resulting from the scoliosis. The electrodes were securely fastened to the skin with adhesive tape and records were taken during certain standard procedures (1) maximal inspiration (2) maximal expiration (3) head raising (4) left lateral flexion of the trunk and (5) right lateral flexion of the trunk. The respective situations of the electrodes (normally two inches apart) were as follows (1) on the lateral abdominal muscles in the anterior axillary line (2) on the rectus abdominis muscle one inch from the median line

TABLE I—RESULTS OF ELECTROMYOGRAPHY IN TYPICAL IDIOPATHIC THORACIC SCOLIOSIS (CASE 30)

Muscle	Side	Inspiration	Expiration	Head raising	Right lateral flexion	Left lateral flexion	Total

(3) on muscles in the sixth intercostal space in the midclavicular line, (4) on the superficial spinal muscles at equal distances (usually 1½ inches) on either side of the spinous processes and at three different levels, and (5) the deep spinal muscles were investigated by touching the laminæ with the needle point and withdrawing the needle about a quarter of an inch

Usually skin electrodes were used, but in addition, whenever possible, recordings were taken from the deep spinal muscles with needle electrodes This requires considerable coöperation from the patient, and needle electrodes cannot be easily used in small children Electromyography was also used for investigating muscle activity in a large number of healthy adults and gives an accurate picture of the electrical activity of the muscle fibres in the vicinity of the electrodes

The usual procedure has been to take recordings from both sides simultaneously during inspiration, expiration, head raising, and right and left lateral flexion of the trunk Thus in most patients about sixty recordings were made, and these were repeated, if necessary, until we were satisfied that we had obtained an accurate and consistent record

On each movement activity was assessed on an arbitrary scale of 0–5 The figures for each side were then added If the ratio between the sums of the figures for each side was less than 2 1, the difference was considered insignificant and activity was recorded as equal If the difference was greater than 2 1 it was considered significant

In tables III and IV "ipse" means that the muscles on the same side as the convexity of the major curve ar significantly stronger, and "contra" means that th muscles on the concave side are significantly stronger (0) indicates that the ratio was between 2 1 and 3 1 and (+) that the ratio was over 4 1, otherwise the was between 3 1 and 4 1

Although the numerical assessments are somewh arbitrary they were always done by the same observ (H F V R), who is experienced in electromyograph and did not know the clinical assessment of the patien The details of one typical investigation are set out table I, the summaries of six typical ones in table II, the summaries of all the recordings in table III, and th salient features in table IV For the sake of brevity an clarity only the recordings from the spinal muscles the apex of the major curve are recorded in table II although recordings were taken from at least three leve in nearly all the patients

† Neurofibromatosis

‡ Case 59 is perhaps not strictly comparable to the others in that he was an adult, the cause of the scoliosis was an acute spasm which disappeared under anæsthesia, and it was a pure lateral flexion with little rotation It is included because the mechanism of production of the scoliosis contrasts with what was found in most of the other cases It illustrates what one would expect—i e, that scoliosis can be produced in more than one way

Ipse the muscles on the same side as the convexity of the curve are stronger *Contra* the muscles on the opposite side to the convexity of the curve are stronger

(0) Ratio between 2 1 and 3 1 (+) Ratio of more than 4 1
Remaining ratios between 3 1 and 4 1

Results

In 57 of 59 patients examined no significant asymmet of diaphragmatic excursion was observed In the others diaphragmatic herniæ were associated wi congenital scoliosis

The results of electromyography of intercostal, abdom nal, and spinal muscles are expressed in tables III and I

No significant correlation was found between imbalan of intercostal and abdominal muscles and the directi of deformity

In 15 out of 20 cases of paralytic thoracic scoliosis and 4 out of 8 cases of paralytic lumbar scoliosis the muscles the apex of the curve were significantly stronger on th convex side (often many times as strong as those on th other side) Of the remaining 9 cases the muscles we equal in 8, but in 7 of these the needle electrodes cou not be used In 1 case the muscles were definitely weak on the convex side

In 16 out of 19 idiopathic curves the muscles on the conve side were significantly stronger at the apex of the curv

Of 9 cases of congenital scoliosis the convex musc were stronger in 4, the concave muscles in 2, and the t sides equal in 3

In 8 cases (3 paralytic and 5 idiopathic) the muscle appeared equal or the concave muscles were stronge when superficial electrodes were used, but with needl electrodes the deep muscles were found to be considerabl stronger on the convex side In other cases, even thoug the convex muscles were slightly stronger with surface electrodes, the difference was far greater with needle electrodes (table II)

Interpretation of Results

In 16 of 19 idiopathic curves the muscles on the concave side were significantly weaker than normal We

TABLE IV—SUMMARY OF SALIENT FEATURES

Type of scoliosis	No of cases	Side of stronger muscles	No of cases in each category at each site

e In this case needle electrodes were not used
f In 1 case stronger muscles were "ipse" with needle electrodes

gest that in some cases at any rate the most likely se for this is an unrecognised attack of poliomyelitis r findings support the theory that some cases of opathic scoliosis are really paralytic

If we now consider cases with much imbalance of the nal muscles—i.e. the known paralytic cases and the pathic cases, which are probably paralytic—we find at the weaker muscles are nearly always on the concave This is the opposite of what one would expect if deformity was caused by imbalance of the longitudinal muscles unopposed action of the longitudinal scles would tend to cause a curvature concave on the nger side

We suggest that in most of the cases we have examined, imbalance of the deep rotator and transverse muscles at is the main factor in producing deformity and that first stage in the genesis of scoliosis in such cases is rotation deformity due to unopposed action of the p spinal muscles. Our findings with needle electrodes firm this hypothesis

Summary and Conclusions

Muscle activity was investigated by electromyography 59 patients with scoliosis

In the overwhelming majority of these especially in alytic cases the spinal muscles were significantly nger on the convex side at the apex of the curve

Probably in nearly all paralytic and many idiopathic ses unopposed activity of the deep spinal muscles ses vertebral rotation and initiates the deformity

If muscle imbalance initiates the deformity it should possible to stop progression of the deformity by akening the stronger muscles A simple way of doing is to excise alternate laminæ and transverse processes the apex of the curve on the convex side

REDUCING OBSERVER ERROR IN A 70-MM CHEST-RADIOGRAPHY SERVICE FOR GENERAL PRACTITIONERS

PETER STRADLING
M.D Lond M.R C.P
CHEST PHYSICIAN

R N JOHNSTON
M.D Aberd., M R C.P
ASSISTANT CHEST PHYSICIAN

HAMMERSMITH CHEST CLINIC AND POSTGRADUATE MEDICAL SCHOOL OF LONDON

> *The roentgenogram is only as good as the person interpreting it, and therefore subject to the not inconsiderable limitations of human perception* (Garland 1949a)

THE necessity for dual reading of films to reduce observer error in chest radiography has been strongly emphasised in America and Denmark but as yet little in this country To the best of our knowledge no mass miniature radiography unit in the United Kingdom has adopted this procedure as a routine Indeed in a recent publication concerned chiefly with methods of increasing the efficiency of mass miniature-radiography services the Medical Research Council (1953) does not even mention dual reading

For the past two years it has been the practice in this clinic to offer to all local general practitioners a chest radiograph for any patient they feel requires this examination The responsibility of reporting a single film as normal without seeing the patient is great and it is very important to make the reading of these films as accurate as possible. In addition to under reading due to observer error small lesions may be missed in one of the blind areas of the standard postero-anterior film estimated to total some 25% of the lungs (National Tuberculosis Association 1950)

The problem was how to ensure accuracy without sacrificing simplicity and speed, which are essential in routine clinic work Our previous experience had suggested that the anteroposterior lordotic view might reveal lesions overlooked or concealed behind ribs or clavicles in a postero-anterior film and thus this view was used as a routine with the postero-anterior in an effort to reduce such errors which are inevitable if a single film is reviewed by one reader alone An added advantage of the routine use of two views is the ready elucidation of shadows due to clothing which occasionally cause confusion if seen on one film only

After the system had been in use for a trial period it seemed feasible to assess its value experimentally and to compare the diagnostic value of the additional film and that of an additional reader An experiment was therefore designed to investigate these points during the routine work of the clinic.

Method

For each patient standard postero anterior and antero posterior lordotic views were taken routinely on 70 mm film and read on the roll in groups of 50–100 at weekly sittings by two observers It was decided at the outset *to simplify the trial by excluding bony and cardiovascular* abnormalities from the investigation only shadows thought to represent conditions affecting the lungs pleura

TABLE I—RESULTS DISTRIBUTED ACCORDING TO READERS AND VOTES FOR ACTION

	—	"No action" on both readings	"Action" on both readings	"No action" on postero anterior but "action" on combined reading	"Action" on postero anterior but "no action" on combined reading	Total
		Reader A				
Reader B	'No action' on both readings	I 440	II N = 30 A = 7	III N = 10 A = 0	IV 25	512
	'Action" on both readings	V N = 87 A = 15	VI N = 15 A = 160	VII N = 5 A = 2	VIII N = 8 A = 1	293
	"No action" on postero anterior but "action' on combined reading	IX N = 13 A = 1	X N = 3 A = 6	XI N = 0 A = 3	XII N = 1 A = 0	27
	Action' on postero anterior but no action' on combined reading	XIII 136	XIV N = 13 A = 3	XV 0	XVI 16	168
	Total	692	237	20	51	1000

and diaphragm were included The definitions of "normal" and "abnormal" would have presented some difficulty, so the problem was simplified by substituting "no action" and "action" Films had to be classified in one of these two groups by each reader on each reading, and it was found that the clinic routine was smoothly maintained by this classification, for it was the one used in practice when operating the X-ray service

To obtain independent assessments of the films each of the two readers (A and B) viewed them alone at separate sessions, recording his reports on the patients' record cards immediately This method abolished transcription errors since no secretary or written report intervened between the reading and the recording Furthermore, by using a punch card the subsequent analysis was facilitated

For the purpose of this trial two clip holes only were provided on the card for each reader the first for recording the report on the reading of the postero-anterior view alone before looking at the anteroposterior lordotic view, and the second for the combined report on the two films after seeing the anteroposterior lordotic view (this reading might confirm or refute the initial interpretation of the postero-anterior view alone) By not clipping or clipping each hole a report of "no action" or "action necessary" could be recorded on each reading, giving four possible combinations for each reader

(1) "No action" recorded for the postero anterior reading alone and for the combined report

(2) "Action necessary" recorded for the postero anterior reading alone and for the combined report

(3) "No action" recorded for the postero anterior reading alone but the combined report recorded as "*Action necessary*"

(4) "Action necessary" recorded for the postero anterior reading alone but combined report recorded as ' No action "

Only if either reader recorded "action necessary" on his combined report (postero anterior and anteroposterior lordotic), even if the other disagreed, was the patient recalled for appropriate large films The notations "N" and "A" ("normal" and "abnormal") were then applied to these cases to indicate the final agreed (or if necessary arbitrated) report on the further views Arbitration was necessary in very few cases, and the opinion of a senior radiologist was accepted

The interval (1 week) between the original small films and the subsequent large ones was sufficiently short to render negligible any errors due to change or disappearance of lesions in that time

A preliminary survey of about 200 cases revealed that at least 1000 would be required to reach any firm conclusions, and this number is here presented Records of a few more than 1000 cases were prepared, but 3 of the first 1000 had to be excluded subsequently because of failure to obtain large films The next consecutive 3 of the number over 1000 were then drawn on to produce the round figure to work with

Results

The findings on analysis of the 1000 cases are set out in table I, in which the squares are numbered consecutively with Roman numerals for ready reference A report of "no action" on all 4 readings was recorded fo 440, and these were accepted as "agreed normals' without further investigation (square I)

The other possibilities are displayed in the appropriat squares with the results of subsequent agreement (o arbitration) on large films indicated (N or A) By th addition of all those with the notation "A" a figur of 198 is obtained for the total "agreed abnormals' Percentages are related to this figure

By appropriate additions and subtractions of th figures presented in table I it is possible to assess th performance of the two readers and the value of addin readings or views to the reading of the standard poster anterior film The main significant findings are given i table II and show similar trends, varying in magnitud for the two readers For either, the lowest yield of th agreed abnormals is given by a single reading of th postero anterior films alone (89% and 91%) The figures can be increased to 98% when both readers mak a single independent report on the postero anterior fil alone The addition of a reading of the anteroposter lordotic view increased the abnormality yield for eac reader alone (to 91% and 94%) but not so effectively did dual readings of the single postero anterior film I fact dual reading of a single postero anterior film misse only 4 of the "agreed abnormals" (3 in square XI, in square IX) Furthermore on investigation these abnormalities proved to be minor shadows of doubtf significance The relative value of the methods in detec ing abnormals can be expressed graphically by usin the figures for the number of agreed abnormals misse by each procedure, and this is shown in fig 1

In assessing the true value of the various combinatio of readings the yield of abnormalities should be relate

TABLE II—COMPARISON OF RESULTS OBTAINED BY DIFFEREN READERS AND METHODS

Reader	Films read	No of agreed abnormals discovered	Agreed abnormals discovered as % of total agreed abnormals	Norma recall
A	Postero anterior alone	177	89	111
	Postero anterior and anteroposterior lordotic	181	91	76
B	Postero anterior alone	181	91	[illegible]
	Postero anterior and anteroposterior lordotic	188	94	13
Both	Postero anterior alone	194	98	34*
	Postero anterior and anteroposterior lordotic	198	100	[illegible]

patients called for further films who subsequently proved normal ("normal recalls") These are presented in the last column of table II It will be seen that single readings of the postero-anterior film gave high figures for normal recalls (particularly in the case of reader B) The addition of the second view however had a striking effect in reducing the number of normal recalls (from 111 to 76 for A, and 280 to 132 for B) The corresponding figures for dual reading show an equally striking saving when the anteroposterior lordotic view is added, and are presented graphically in fig 2 Had the lordotic view not been used in this trial an additional 157 patients would have been recalled This group has been termed "unnecessary recalls."

Discussion

The pioneer work in this field has come from America, where Yerushalmy and others (Yerushalmy 1947, Birkelo et al. 1947, Yerushalmy 1949, Garland 1949b Yerushalmy et al. 1950, Yerushalmy 1953) have reached the following broad conclusions:

(1) There is considerable subjective error in interpreting films (about 25% in these series)

(2) This can best be reduced by an independent second reader.

(3) Differences due to different types of film (e.g 35 mm and 14×17 in.) are negligible compared with the reader variation.

(4) The closest agreement between readers was obtained by ing descriptive reporting by a simple decision on "action" or "no action."

These conclusions are probably generally applicable Fletcher and Oldham (1949) Groth Petersen et al (19), and Cochrane and Garland (1952) have shown observer errors of similar magnitude Holm et al (1954) have re-emphasised the importance of independent dual reading

The Lancet (1954) while noting that previous work on this subject had often been under special test conditions suggests that under normal working conditions the consistency might be far greater It would be interesting to compare the results with those of an experiment made in the course of routine work and involving their routine decisions." Our results in routine practice confirm the tation of previous workers that independent dual reading reduces subjective error It will be seen that under reading when view single postero anterior films is 9–11%

In considering error which lower than that found by previous workers, factors may of some importance

(1) Whereas Yerushalmy's figures to minimal tuberculous lesions, our series contains the mixed abnormalities observed in routine practice— of them gross lesions.

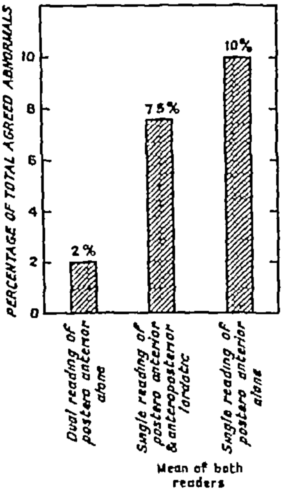

Fig 1—Agreed abnormals missed by various reading methods

(2) The agreed abnormals in Yerushalmy's papers are relatively small groups—61 of 1256 and 30 of 1790 We were fortunate to be dealing with a group containing a higher proportion of abnormals—108 of 1000

(3) The lack of an independent panel to define the "agreed abnormals" may have operated in our favour

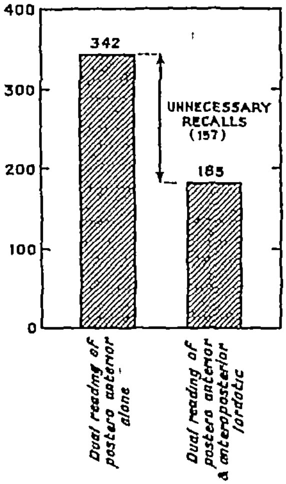

Fig 2—Normal recalls.

The anteroposterior lordotic film has certainly been of value in reducing observer error but more in avoiding "unnecessary recalls" than in increasing the abnormality pick up rate especially for reader B When it is remembered how much personal anxiety and loss of time these unnecessary recalls cause the anteroposterior lordotic view fully justifies the slight increase in staff time and expense In fact when 70 mm film is used double views, more expensive initially will ultimately reduce cost if patients recalled are radiographed on large film We consider that the result shown in fig 2 is as important as that in fig 1

Nearly nine years have elapsed since the presentation of the first paper on this problem and the chief conclusion —the importance of a second reading—is still neglected in this country It is probably natural to acknowledge blandly fallibility in others but not in oneself and this may explain reluctance to insist on dual reading We agree that an observer-error test is a "chastening experience" (Lancet 1954) and any who doubt this should themselves try the experiment

Objections to dual readings on the grounds of inadequate staff can surely be overcome Even when a second reader cannot be found a second independent reading by the same person can considerably reduce observer error (Yerushalmy et al 1950); it is hard to justify the continued practice of single reading of single films in routine chest radiography

Summary and Conclusions

In an effort to find a simple way of reducing observer error in a 70 mm chest radiography service single readings of one and two views were compared with dual readings of the same films

Two observers independently reading a single postero anterior film achieved greater accuracy than either alone

The addition of an anteroposterior lordotic view increased the abnormality yield of either reader working alone but was not so effective as the single view read by two observers.

Adding the lordotic view was of greatest value in avoiding unnecessary recalls

The best results were obtained by dual reading of the two views thus combining the advantages of both methods

Dual reading is essential in radiographic surveys and the routine use of the second view is of very great value in saving unnecessary anxiety time and expense

We sincerely thank Dr V H. Springett and Dr C M Fletcher for much help and advice during the trial and for constructive criticism of the manuscript, Dr R E Steiner for reading the films where arbitration was necessary, and Miss A. Keeble and Miss E Mangan for the radiography

THE STERILISATION OF BLANKETS WITH CETYL TRIMETHYLAMINE BROMIDE*

ROBERT BLOWERS
M D Lond, Dip Bact
DIRECTOR

K R WALLACE
M B Camb, Dip Bact
ASSISTANT BACTERIOLOGIST

PUBLIC HEALTH LABORATORY (MEDICAL RESEARCH COUNCIL), MIDDLESBROUGH

It is well established that, in hospitals, blankets are an important reservoir of pathogenic organisms, and that freshly laundered blankets may be as heavily contaminated as those in use (Deicher 1927, van den Ende et al 1940, Thomas and van den Ende 1941, Rountree and Armytage 1946, Steingold et al 1954) The usual method of laundering blankets by a low-temperature wash does not sterilise them, and autoclaving is unsatisfactory because it produces gross shrinking and felting Oiling reduces the dissemination of particles from blankets, but there are objections to this process it is difficult to control, and the blankets may be unpleasantly oily, moreover, after some methods of oiling, organisms are still present

The use of quaternary ammonium compounds to sterilise blankets has been suggested by several workers

Rountree (1946) used an oil water emulsion stabilised with cetyl pyridinium bromide ('Fixanol C') Blankets treated with this emulsion were bactericidal for hæmolytic strepto cocci sprayed on to them from broth cultures Barnard (1952) also used fixanol C but did not oil the blankets Virtual sterility of both naturally and artificially contaminated blankets was obtained and some degree of residual bacteriostatic ability was noticeable

Steingold et al (1954) used tetra decylpyridinium bromide and alkyldimethylbenzylammonium chloride on naturally contaminated blankets and found very low bacterial counts after treatment

Vaughn et al (1948) rejected quaternary ammonium compounds because of their indefinite action in the presence of anionic synthetic detergents and soap

Objections to fixanol C are that it has an unpleasant odour, that it stains the blankets, and that it does not dissolve easily We therefore decided to try cetyl trimethylamine bromide, which is marketed as 'Cirrasol OD' (Imperial Chemical Industries Ltd) It is an odourless colourless cationic surface active agent which dissolves easily in water

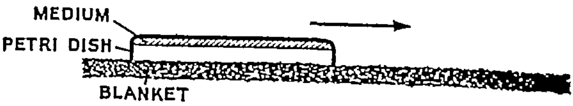

Fig 1—Method of sampling blankets.

Some of the previous work on the sterilisation of blankets is unrealistic in that artificially contaminated blankets were used and no attempt was made to neutralise residual disinfectant activity in the samples for culture In any experiment designed to test the bac properties of a chemical substance it is essential th samples taken for culture should be so treated that any of the disinfectant remaining in them (and possibly attached to viable bacteria) is neutralised If this is not done, the bacteriostatic properties of the substanc under test may prevent the growth of surviving organism and thus give rise to misleading results

We have worked entirely with blankets contaminate naturally while in use in hospital wards, and have incorporated in our culture medium a neutralising substanc for cetyl trimethylamine bromide

Materials and Methods

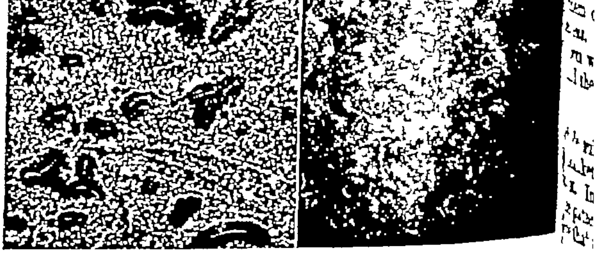
Cirrasol OD is an aqueous paste containing abou 12 5% of technical-quality cetyl trimethylamine bromid The consistence of the paste varies with the temperatur but the paste dissolves easily in warm water

Blankets were taken at random from those comm into a hospital laundry from medical and surgic wards

Sampling —The samples were taken by the swee plate technique This method was shown to us b Dr R E O Williams The blanket is laid flat on a tabl or may be sampled in its normal position on the be A petri dish containing a suitable culture medium, pressed upside down firmly against the blanket and swe across it fairly rapidly and evenly (fig 1) The moveme of the edge of the plate causes particles of dust an fluff to be thrown on to the surface of the medium Aft a little practice it is possible to adjust the pressure movement so that each plate is evenly spread with abo the same number of visible particles

The *culture medium* was nutrient agar containin 0 75% of 'Perminal COL'† It effectively neutralise any cirrasol OD which might remain active in the samp (fig 2) The colonies were counted after the plat had been incubated at 37°C for eighteen hours

Laundry Methods —The test blankets were washed i a Manlove and Alliot 34 × 54 in open pocket machin fitted with interrupter gear so that the inner contain is rotated intermittently This arrangement is bett than continuous rotation because it causes less felting an hardening of the blankets For a full load the machin was filled with water at a temperature of about 98°



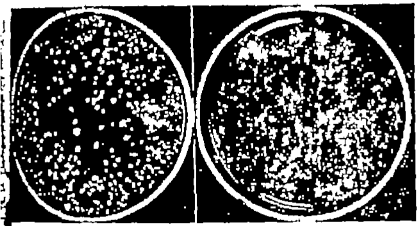
a *b*

Fig 2—Fibres from cirrasol-treated blanket causing: *a*, inhibition of *Staph aureus* on nutrient agar; *b*, no inhibition on perminal-agar

---

* This work forms part of an investigation by the Public Health Laboratory Service for the Newcastle Regional Hospital Board and is partly financed by a grant from the regional board

† Made by Imperial Chemical Industries Ltd, this is a mixture of non ionic surface active agent of the fatty alcohol/ethyle oxide type together with an anionic agent of the highly sulphate oil type



a b

1—Sweep-plates from blanket before (a) and after (b) treatment with cirrasol OD

7°C) to give a standing dip of 14 in Half a pint of Lissapol N'‡ and about 2 oz of soda ash (anhydrous dium carbonate) were added, and the machine was run for six minutes This was followed by one three minute rinse. The machine was next refilled with water at the same temperature as the wash to give a standing dip of 14 in., and 2½ pints of cirrasol OD was added to give a concentration of cetyl trimethylamine bromide of about 0 036% The blankets were left in this solution for minutes with occasional rotation They were next hydro-extracted and dried in warm air

The use of a non ionic detergent for washing is important. Soap and many other detergents are anionic and traces of them remaining in the blankets may inter with the action of the cationic cirrasol OD

ontrol blankets were treated by the routine method d in the laundry This involved washing with an ionic detergent followed by two rinses in water

Results

Treatment with cirrasol produced blankets from which ly occasional organisms were isolated (fig 3) The n colony-counts on 78 blankets before and after

TABLE I—SWEEP PLATE COUNTS ON 12 BLANKETS BEFORE AND AFTER TREATMENT WITH CIRRASOL OD

General bacterial counts on sweep-plates		General bacterial counts on sweep-plates	
Before treatment	After treatment	Before treatment	After treatment
2080	1	389	0
2300	10	313	7
1800	3	328	1
900	11	205	0
411	1	251	0
310	1	240	[illegible]

tment were 104 and 2 6 respectively In contrast routine washing procedure was much less effective mean counts for 42 blankets before and after washing re 340 and 208 respectively Tables I and II show the nts on the 12 most heavily contaminated blankets m each series.

After treatment with cirrasol the blankets were of mal appearance and texture and odourless. We were ble to show that cirrasol remained in the blankets by laing them over culture plates sown with *Staphylococcus aureus* After incubation the growth of the phylococci was completely inhibited in well marked s round the pieces of blanket fibre (fig 2a)

Discussion

The whole subject of the washing and sterilisation of hospital blankets deserves more thought than is often given to it. In many hospitals blankets are washed only if the patient dies or has had an infectious disease We believe that this is not only wrong but also dangerous. Many workers have now shown that patients in hospital quickly become nose and skin carriers of antibiotic resistant staphylococci Blankets are largely responsible for the transfer of these organisms from patient to patient, and should be washed and sterilised afresh for each new occupant of the bed Possibly this routine would be more acceptable to hospital authorities if the great damage done to blankets by heat sterilisation could be avoided.

The efficacy of quaternary ammonium compounds for the sterilisation of blankets has been suggested by the results of other workers who did not, however, neutralise residual disinfectant remaining in the blankets Their results have thus failed to show that organisms in the blankets are killed. The experiments reported here show that susceptible organisms are actually killed and not merely inhibited on the culture plates Sterilisation of blankets with cirrasol is simple and should be used as a routine procedure in hospital laundries The only precaution necessary is to ensure that preliminary washing is done with a non ionic detergent The first treatment of old blankets by the process we have described sometimes gives unsatisfactory results, but subsequent treatments achieve near-sterilisation We think that this is because the blankets contain a residue of soaps or of anionic detergents in which they were previously washed, which partly neutralises the bactericidal properties of cirrasol

TABLE II—SWEEP PLATE COUNTS ON 12 BLANKETS BEFORE AND AFTER WASHING WITH ANIONIC DETERGENT

General bacterial counts on sweep plates		General bacterial counts on sweep plates	
Before washing	After washing	Before washing	After washing
2000	740	800	190
7000	776	622	1028
2000	1332	600	600
1400	716	528	640
1028	260	379	75[illegible]
972	860	170	404

Cirrasol OD is less active against *Pseudomonas pyocyanea* than against many other organisms. It is, however, highly active against *Staph aureus* and this is of great value because of the increasing prevalence of infection of surgical wounds by antibiotic resistant staphylococci.

We have not yet been able to show to what extent cirrasol treated blankets retain disinfecting ability and hence influence the number of airborne organisms in the wards during bed making

The cost of the treatment above that of normal laundering is about 3½d a blanket The washing and sterilisation are however done as a continuous process, and separate handling of blankets, as in autoclaving is avoided The cost of the materials is therefore offset by a saving in labour

Summary

Blankets are an important reservoir of pathogenic organisms, because the routine low temperature wash does not sterilise them By a simple sweep plate technique large numbers of organisms were isolated from them

A method is described whereby blankets are treated with cetyl trimethylamine bromide applied in a laundry washing machine After this treatment only a few organisms were isolated

As distinct from similar previous work with quaternary ammonium compounds sampling was done on neutralising media to avoid misleading results from residual disinfectant in the samples for culture

We wish to thank Imperial Chemical Industries Ltd for providing materials and for technical advice Mr R I Aston for advice and assistance the laundry staffs at Poole Hospital Nunthorpe and at Crossgate Hospital Durham for their participation in the trials and Mr W R I Hollingsworth for some of the photographs

ESTIMATION OF BLOOD-OXYGEN SATURATION

A NEW CUVETTE

C P HANDFORTH*
B Sc, M.B Lond
From the Department of Medicine, St Thomas's Hospital Medical School, London

Millikan (1942), Wood (1950), and others have described methods for the photo electric determination of the oxygen saturation of blood, but their apparatus is not generally available I describe here a simple optical cuvette for use in the Evan's portable photo electric colorimeter A preliminary report has been published (Handforth 1953)

Construction

The optical cuvette is constructed from 0 5 mm bore 'Polythene' tubing wound in a spiral over a 'Perspex' tube (fig 1), black silk is wound over the polythene spiral so as to lie between adjacent turns and occlude any light which has not passed through the lumen of the tubing The projecting ends of the perspex tube are painted black for the same reason The capacity of the cuvette is 0 2 ml and it may be used to analyse 0 5 ml samples

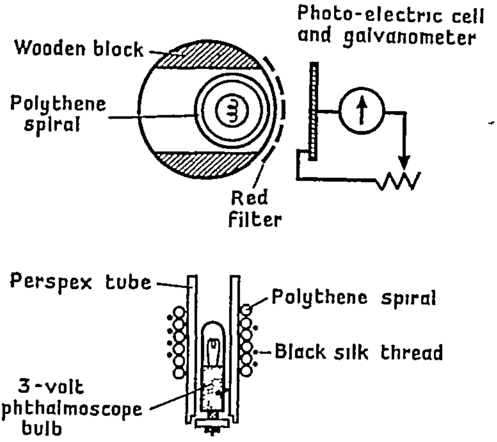

Fig 1—Diagram of apparatus The filter transmits only light above 600 Angstrom units and the photo-electric cell does not respond above 8000 A°

The source of light is an ophthalmoscope bulb placed inside the perspex tube, for zero adjustment of the galvanometer suitable resistances are placed in series with this bulb and in the photo electric-cell galvanometer circuit

The assembled cuvette and light source is mounted in a black perspex or wooden block with a window on one side covered with a red filter (Ilford 205 or Wratten 29), the block fits into the colorimeter

Calibration

The colorimeter has a logarithmic scale from zero to infinity The cuvette is filled with isotonic saline and the galvanometer set to infinity with the light off and to zero with the light on

To calibrate the oximeter a blood of known hæmoglobin content is serially diluted and the optical densities of fully oxygenated and fully reduced samples are measured (the blood is fully reduced with sodium hydrosulphite) Fig 2 shows the optical density curves for fully oxygenated and fully reduced blood plotted against the hæmoglobin values

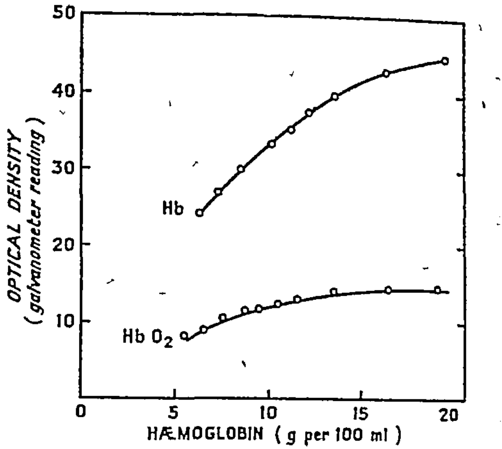

Fig 2—Optical-density curves for fully oxygenated and fully reduc blood of different hæmoglobin values.

It has been found that the difference in optical densit betw the fully reduced sample and the fully oxygenated sample blood is always the same for a given hæmoglobin value, fig 3 (uncorrected line) follows simply from fig 2

Method

For determining the percentage oxygen saturation any sample only two readings of the optical densi are needed (1) that of the sample on collection, and that of the sample after full oxygenation The opti density of a fully reduced sample is difficult to meas correctly, but it may be predicted from fig 2

Thus if a sample of blood is found to have an optical dens of 29 and the fully oxygenated sample an optical density 15, and the total hæmoglobin is 15 6 g per 100 ml., th the optical density of the fully reduced sample would 15 + 28 = 43 The percentage saturation would

$$\frac{43-29}{43-15} \times 100 = 50\%$$

In general terms $\frac{\text{reduced reading}-\text{test reading}}{\text{reduced reading}-\text{oxygenated reading}} \times$ = percentage saturation

The estimations are unaffected by the presence bile-pigments or plasma lipids, as these do not al the ratio of the optical density readings betwe reduced and oxygenated blood Errors in the hæm globin estimations have relatively little effect on calculated oxygen saturation because of the shall slope of the graph in fig 2 Moreover, it is usu unnecessary to repeat the fully reduced or fully saturat readings in a series of samples of the same blood Wh an absolute figure for oxygen content is required, estimation of the oxygen capacity is made by manometric method described by Van Slyke and N (1924)

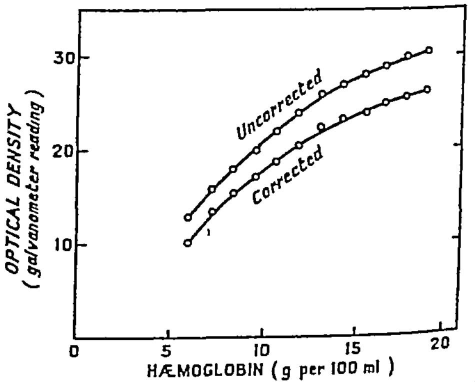

Fig 3—The difference in optical density between fully oxygenated and fully reduced blood for different hæmoglobin values.

4—Linear relationship between percentage oxygen saturation as ermined with the oximeter and by the manometric method of n Slyke.

racy

When a series of estimations are carried out and pared with the results obtained with the mano ric method of Van Slyke and Neil (1924) the relation p is found to be linear (fig 4) but there is a systematic r which in the above example is + 14% at 0% ration This error depends on the quantity of ium hydrosulphite added to the samples in order to ain the readings recorded in fig 2 The values plotted the uncorrected line in fig 3 are therefore corrected reducing them by 14%

METER READINGS OF PERCENTAGE OXYGEN SATURATION ORRECTED VALUES) ON 25 SAMPLES, WITH THE RESULTS TAINED ON THE SAME SAMPLES BY THE MANOMETRIC ETHOD OF VAN SLYKE

IDIOPATHIC GRANULAR PROCTITIS

C F J Cropper
O.B E B.A. Oxfd F.R C P E.
PHYSICIAN BONKSWOOD HOSPITAL, WORCESTER

Published reports on idiopathic granular proctitis are surprisingly few and textbooks usually omit it from the differential diagnosis of rectal bleeding Price's (1947) index does not mention it

Brooke's (1954) description cannot be excelled:

> non specific procto sigmoiditis an insidious and indolent condition of the distal end of the large bowel has been observed by many but recorded by few A mild chronic and intractable inflammation is to be seen in the lowermost part of the rectum often limited to the last two or three inches with a sharply defined upper limit less frequently its distribution throughout the rectal ampulla is patchy On proctoscopy the rectal mucosa in the area involved is granular and bleeds to the touch Over the course of years the inflammation may spread upwards to involve the sigmoid and at this stage the sigmoidoscopic appearance is not dissimilar from that found in ulcerative colitis the onset is insidious and slow and there is no constitutional upset except when secondary anæmia results from constant blood loss.'

The condition is however distressing to the patient and a social handicap since the presence of blood in the rectum is apt to precipitate *diarrhœa*.

Sigmoidoscopic recognition is easy there is complete loss of the normal satiny sheen of the mucosa (Cropper 1945) whose place is taken by a coarse roughening of the surface due to the exposure of the deeper layers of the membrane.

The inflammation fluctuates unpredictably and no treatment can be regarded as specific

Since idiopathic granular proctitis has been so seldom described, I review here my own series of 26 cases (see table) This series excludes all cases of secondary granular proctitis, which fall into two groups those in which the granularity is a forerunner or concomitant of true ulcerative colitis; and those due to recurrent amœbic dysentery In both these groups the appearances are identical with those of idiopathic granular proctitis but in ulcerative colitis actual ulceration of the mucosa can often be seen with or without blood and pus flowing down from higher levels Such evidence of actual ulceration rules out by definition the diagnosis of idiopathic proctitis Similarly granulation occurring as a stage in recurrent amœbic dysentery must almost invariably be regarded as a sequel of acute amœbiasis. Evidence of its amœbic origin will be forthcoming from the history or from serial sigmoidoscopies at which scrapings from ulcers contain entamœbæ In many cases the metamorphosis over months of ulcers into pin point craters (Cropper 1945) and perhaps of craters into granularity eliminates benign proctitis from the diagnosis

Material and Findings

I have kept detailed records of about 2300 patients chiefly ex Servicemen involving about 2800 endoscopies between November 1946 and July 1954 11 of these presented with granular proctitis associated with ulcerative colitis 7 with granular proctitis following amœbic dysentery and 26 with the idiopathic granular proctitis Although 21 of these 26 patients had served in the tropics and most of them had been labelled dysentery' at some time in their service careful study of their history and repeated sigmoidoscopies and stool examinations provided convincing evidence of a non-dysenteric picture

This work was initiated when I was appointed to the then Ministry of Pensions Therefore most of the material

ANALYSIS OF CASES OF IDIOPATHIC GRANULAR PROCTITIS

Case no	Tropical service	Length of observation	Complications at sigmoidoscopy	No of sigmoidoscopies	Reply to final questionnaire	Original diagnosis
1	Yes	2 mos	Nil	2	No reply	Bacillary dysentery
2	No	1 yr	Nil	3	Asymptomatic	Granular proctitis
3	Yes	4 yr	Polyps	5 (1 almost normal)	Persistent blood	Amœbic dysentery
4	No	4½ yr	Nil	3 (1 normal)	Blood on and off, gaining weight	
5	Yes (P O W)	3½ yr	Nil	4 (1 normal)	Blood on and off, about 5 stools daily	
6	Yes	3½ yr	Nil	1	Diarrhœa only	Amœbic dysentery
7	Yes (P O W)	4½ yr	Polyps	4	Blood every few weeks	
8	Yes	4 yr	Nil	3	Periodic blood and diarrhœa	Amœbic dysentery
9	Yes	14 mos	Nil	2	No reply	
10	Yes	6 yr	Nil	3	Bouts of blood in spring	Clinical dysentery
11	Yes	6 yr	Nil	4	Diarrhœa and blood	Amœbic dysentery
12	Yes	5 yr	Nil	2 (1 normal)	Blood in attacks, weighs 14 st	
13	Yes	5½ yr	Nil	8 (2 normal)	Blood very occasionally, very fit	
14	No	4 yr	Nil	5	Blood now and again, no gain in weight	Dysentery
15	Yes	5 yr	Nil	5	Constant diarrhœa with blood and mucus, weight fluctuating	
16	No	1 yr	1 small polyp	4 (1 normal)	No reply	
17	Yes	4½ yr	1 polyp	2	Asymptomatic	Ulcerative colitis
18	Yes	4 yr	Nil	4 (1 normal)	Still passing blood general health good	Amœbic dysentery and bacillary dysentery
19	Yes	7 mos	Nil	3 (1 almost normal)	No reply	Amœbic dysentery and bacillary dysentery
20	No	4 yr	Nil	1	Loose stools, no blood very fit	Granular proctitis
21	Yes, 1916 in Mesopotamia	3 yr	Nil	3 (1 normal)	Blood ceased 12 months ago, generally much better	Dysentery
22	Yes (P O W)	3 yr	Nil	2	Asymptomatic	
23	Yes	4½ yr	Nil	5	4 motions a day, no blood or mucus weight static	Amœboma
24	Yes	3 yr	Nil	5	No reply	
25	Yes	3½ yr	Nil	5 (2 normal)	Blood rarely, general health good	Amœbic dysentery and bacillary dysentery
26	Yes	3½ yr	Nil	3	Diarrhœa and blood, always passes a trace of blood	Amœbic dysentery and bacillary dysentery

represents a selected group Temporary residence in the tropics is not, however, to be regarded as an ætiological factor, nor is the fact that all the patients were male more than fortuitous Among general hospital patients idiopathic granular proctitis affects both sexes in roughly equal proportions (B N Brooke, personal communication)

The patients marked P O W in the table were in Japanese hands and therefore virtually deprived of diagnostic or therapeutic facilities for the first few years of their "dysentery" in these cases the past history of the disease was particularly obscure

The length of observation shown in the table is the period from when the patient was first seen by me until the date of the follow-up letter In 4 cases sigmoidoscopy was done at the end of the period of observation, which in all 4 cases was about four years

The follow-up letters show that in no case was the patient obliged to lose more than an occasional week's work thus even in cases with a six year history no gross deterioration has taken place In case 21 the disease has lasted more than thirty years without causing much inconvenience to the patient

Discussion

It is important that this syndrome should be clearly defined and kept in mind whenever rectal bleeding is under consideration If it can be diagnosed with precision, the patient can be assured that his disease is comparatively harmless, this is of great importance because rectal bleeding usually fills the patient with alarm and apprehension, and he is likely to torture himself with possibilities which he hardly dares to mention

There can be no doubt whatever that a very large number of patients with idiopathic granular proctitis were hastily and uncritically diagnosed as having some form of tropical dysentery and treated as such Indeed tracing back the history of such cases leads one into a tangle of vague diagnoses which in retrospect is impossible to unravel

The upshot of this is that, if the syndrome were widely recognised, the evacuation of personnel from forward areas would be minimised, and many an innocent victim would be saved from ill advised, expensive, unnecessary and often harmful therapy

I have often thought that the Forward Malaria Treatment Unit evolved in the late war might well be paralleled by a Forward Dysentery Treatment Unit, where the sigmoidoscope and the microscope could be used within sound of the guns Such a unit would be of incalculabl value in promoting immediate treatment of the tru dysenteries, and the immediate return to the front lin of patients with granular proctitis

Note on Treatment

It is my impression that phthalylsulphathiazol suppositories (Cluer 1947) have a place, albeit smal in controlling idiopathic granular proctitis It is tru that, since no infective agent has been incriminated, th use of an antibacterial drug is empyrical Plain coco butter suppositories are probably just as effective, an it is worth prescribing these, particularly in periods o quiescence Although severe secondary anæmia was no observed in this series it can develop (B N Brooke personal communication) and would indicate iro therapy Probably the most valuable part of thi treatment is reassurance

Summary

26 cases of idiopathic granular proctitis are reviewed

The recognition of this syndrome is important, so that it can be clearly distinguished from the more serious conditions of which it may be a forerunner, a concomitant or a sequel

I wish to thank Mr B N Brooke for his advice during the preparation of this article Seeing that war pensioners medical documents have been used, it is fitting that acknowledgment should be made to the Ministry of Pensions and National Insurance for permission to use these records.

Reviews of Books

Diagnosis and Treatment of the Acute Phase of Poliomyelitis

And its Complications Editor: ALBERT G BOWER, M.D Baltimore: Williams & Wilkins London Baillière Tindall, & Cox. 1955 Pp 250 50s

THIS authoritative and timely statement of American practice comes from the Los Angeles County Hospital—second largest communicable-disease hospital in the United States—and it is based on an experience of over 15,000 cases, 11,000 of them in the last seven years The main clinical problems are dealt with in turn by the editor and other physicians, by the nurse, otolaryngologist, radiologist, physical medicine specialist, obstetrician, biochemist, and other experts. The team is united in its *advocacy of early elective tracheotomy* combined with use of the tank respirator for bulbar poliomyelitis with respiratory involvement. Although no statistical evaluation is attempted (except on a small scale in a final chapter by a county medical team which adopted the same methods), the pros and cons of the team's technique seem to have long passed the stage of academic discussion and we are clearly dealing with a fait-accompli.

Technical *requirements are naturally far from simple* the special equipment required by a unit includes a Bennet respiratory ventilation meter for accurate measurement of tidal air and vital capacity a positive-pressure attachment exactly synchronised with the cycle of the respirator a humidifier attachment, an intermittent positive pressure breathing unit of the demand flow type and a juvenile respirator *First-class laboratory facilities for control of* blood chemistry are also required. Finally the well integrated team of medical and surgical specialists and of experienced nurses must be ready for action at any moment Under such conditions results got progressively better Some 60–80% of respirator patients had tracheotomies.

The book is excellently produced and the illustrations are well chosen. Clinicians dealing with acute poliomyelitis will find it stimulating and helpful.

Medical History of the Second World War

The Army Medical Services Administration. Vol. II Editor: F A E CREW F.R.S H.M. Stationery Office 1955 Pp 504 65s

THE subjects of this volume are preventive medicine in its military aspects and other activities of the medical services outside or ancillary to the collection and treatment of the sick and wounded. Nursing dentistry, pathology radiology blood transfusion, psychiatry and ophthalmology—each has a chapter tracing its growth during the war and the *changes in its organisation* to meet the needs of the hour Strictly medical and technical commentaries will appear in later volumes. Administrative detail is likely to make dull reading but those with long memories will find some persuasive explanations of incidents which seemed addle-pated muddling at the time.

Of greater interest and importance are the chapters on "hygiene"—a word which in the Army embraces an empire which must be the envy of the most ambitious nation It came as a shock to some civilians in khaki to find that while they seemed to be more knowledgeable at the bedside (perhaps they had had more practice) the boot was on the other foot when they met the problems of keeping the *Army fit to fight. The Army School of* Hygiene has yet to receive its due of praise for solid research and ingenious innovation War brought to it new problems and this account ranges over the ration scale the design of uniforms, medical categorisation (which might have been expanded) environmental hygiene and the health of those who fought in tanks It really deserves a volume to itself

There are other reasons for reading this book than one which to recapture a taste of the purposeful energy of ten years ago. It is a monument to many anonymous men whose efforts brought victory from near-defeat It includes many hints and suggestions which deserve further inquiry in these quieter days

Operative Orthopedic Clinics

LEWIS COZEN M D F.A C.S assistant professor of orthopedic surgery College of Medical Evangelists, Los Angeles; ALVIA BROCKWAY M.D chief of staff Orthopedic Hospital, Los Angeles; in collaboration with PAUL E MCMASTER, M.D F.A.C.S., clinical professor of orthopedic surgery University of California Philadelphia J B Lippincott London: Pitman Medical Publishing Company 1955 Pp 329 80s

IN their preface the authors say: "An attempt has been made figuratively *to allow the reader to take* his place in the operating room of two busy orthopedic services. After the dictated report, the reader will find some remarks similar to the verbal comment the surgeon might make during and after the actual surgery" And later 'Had the operative reports been dictated more carefully, a more lucid picture of the operation would be *present in many instances* They do not pretend to cover all orthopædic operations, and their choice appears rather haphazard On the whole the *descriptions of* procedures are clear enough, though—with the method they use—there is necessarily much repetition. The main interest however lies in the subsequent comments, which cover a wide field not always directly relevant to the operation under discussion Though it is extremely hard for the reader to get a balanced view of the indications for any *particular procedure he will pick* up many valuable tips on overcoming the difficulties that can arise during operation

The book is largely an account of individual technique, and this of course may differ widely from our own. But it is not easy to believe that displacement of the patella is ever necessary for the removal of an external meniscus or that removal of one-third of the proximal phalanx is sufficient in Keller's operation The illustrations leave *much to be desired, some* being pointless, and others positively misleading Technique can be better learnt, on the whole, from the standard textbooks *on orthopædic* operations but the surgeon with some experience behind him will find much to interest him.

Experimental Psychology

Revised edition. ROBERT S WOODWORTH Columbia University HAROLD SCHLOSBERG Brown University London: *Methuen. 1954 Pp 948 £3 3s*

IN the course of his long life—he was born in 1869—Professor Woodworth has rendered great services to psychology as investigator and teacher; among the most valued of his *contributions has been his* handbook of experimental psychology The historian of this subject, E G Boring said of Woodworth that he "came as near to being the general experimental psychologist as any important man ever did," and the range of his activities and experience justifies this extreme statement. Allied with his exceptional gift for lucid exposition it enabled him to bring out a book *of remarkably* catholic completeness within its declared scope. The first edition appeared in 1938 after eight years of determined work in preparing it. In 1940 Professor Woodworth and his collaborator undertook the present thoroughgoing revision. *The book contains* more material than before but is not bulkier Historical surveys have been greatly reduced and some chapters (e g *on feeling and* experimental æsthetics) have been dropped The magnitude of the authors' task may be gauged from the size of the bibliography—about 2480 titles half of which had not been used for the first edition. The chapters on emotion and *on learning have been* reorganised in accordance with current development in these fields.

This *is not a handbook* of psychology It largely omits for example the field of individual differences, social psychology, much of animal psychology, child development and applied psychology the name of Freud does not appear in the bibliography nor Piaget nor MacDougall It is concerned only with experimental psychology which is not the whole of psychology but the most solid and *communicable* part and that which experimental biologists generally and physiologists in particular will find closest to their own scientific *problems* and habits of thought It is in its own field a masterly standard work.

ANALYSIS OF CASES OF IDIOPATHIC GRANULAR PROCTITIS

Case no	Tropical service	Length of observation	Complications at sigmoidoscopy	No of sigmoidoscopies	Reply to final questionnaire	Original diagnosis
1	Yes	2 mos	Nil	2	No reply	Bacillary dysentery
2	No	1 yr	Nil	3	Asymptomatic	Granular proctitis
3	Yes	4 yr	Polyps	5 (1 almost normal)	Persistent blood	Amœbic dysentery
4	No	4½ yr	Nil	3 (1 normal)	Blood on and off gaining weight	
5	Yes (P O W)	3½ yr	Nil	4 (1 normal)	Blood on and off, about 5 stools daily	
6	Yes	3½ yr	Nil	1	Diarrhœa only	Amœbic dysentery
7	Yes (P O W)	4½ yr	Polyps	4	Blood every few weeks	
8	Yes	4 yr	Nil	3	Periodic blood and diarrhœa	Amœbic dysentery
9	Yes	14 mos	Nil	2	No reply	
10	Yes	6 yr	Nil	3	Bouts of blood in spring	Clinical dysentery
11	Yes	6 yr	Nil	4	Diarrhœa and blood	Amœbic dysentery
12	Yes	5 yr	Nil	2 (1 normal)	Blood in attacks, weighs 14 st	
13	Yes	5½ yr	Nil	3 (2 normal)	Blood very occasionally, very fit	
14	No	4 yr	Nil	5	Blood now and again, no gain in weight	Dysentery
15	Yes	5 yr	Nil	5	Constant diarrhœa with blood and mucus, weight fluctuating	
16	No	1 yr	1 small polyp	4 (1 normal)	No reply	
17	Yes	4½ yr	1 polyp	2	Asymptomatic	Ulcerative colitis
18	Yes	4 yr	Nil	4 (1 normal)	Still passing blood general health good	Amœbic dysentery and bac lary dysentery
19	Yes	7 mos	Nil	3 (1 almost normal)	No reply	Amœbic dysentery and bac lary dysentery
20	No	4 yr	Nil	1	Loose stools, no blood very fit	Granular proctitis
21	Yes, 1916 in Mesopotamia	3 yr	Nil	3 (1 normal)	Blood ceased 12 months ago, generally much better	Dysentery
22	Yes (P O W)	3 yr	Nil	2	Asymptomatic	
23	Yes	4½ yr	Nil	5	4 motions a day, no blood or mucus, weight static	Amœboma
24	Yes	3 yr	Nil	5	No reply	
25	Yes	3½ yr	Nil	5 (2 normal)	Blood rarely, general health good	Amœbic dysentery and bac lary dysentery
26	Yes	3½ yr	Nil	3	Diarrhœa and blood, always passes a trace of blood	Amœbic dysentery and bac lary dysentery

represents a selected group Temporary residence in the tropics is not, however, to be regarded as an ætiological factor, nor is the fact that all the patients were male more than fortuitous Among general hospital patients idiopathic granular proctitis affects both sexes in roughly equal proportions (B N Brooke, personal communication)

The patients marked P O W in the table were in Japanese hands and therefore virtually deprived of diagnostic or therapeutic facilities for the first few years of their "dysentery" in these cases the past history of the disease was particularly obscure

The length of observation shown in the table is the period from when the patient was first seen by me until the date of the follow-up letter In 4 cases sigmoidoscopy was done at the end of the period of observation, which in all 4 cases was about four years

The follow-up letters show that in no case was the patient obliged to lose more than an occasional week's work thus even in cases with a six-year history no gross deterioration has taken place In case 21 the disease has lasted more than thirty years without causing much inconvenience to the patient

Discussion

It is important that this syndrome should be clearly defined and kept in mind whenever rectal bleeding is under consideration If it can be diagnosed with precision, the patient can be assured that his disease is comparatively harmless, this is of great importance because rectal bleeding usually fills the patient with alarm and apprehension, and he is likely to torture himself with possibilities which he hardly dares to mention

There can be no doubt whatever that a very large number of patients with idiopathic granular proctitis were hastily and uncritically diagnosed as having some form of tropical dysentery and treated as such Indeed tracing back the history of such cases leads one into a tangle of vague diagnoses which in retrospect is impossible to unravel

The upshot of this is that, if the syndrome were widely recognised, the evacuation of personnel from forward areas would be minimised, and many an innocent victim would be saved from ill-advised, expensive, unnecessary and often harmful therapy

I have often thought that the Forward Malaria Trea ment Unit evolved in the late war might well be paralleled by a Forward Dysentery Treatment Unit, where th sigmoidoscope and the microscope could be used withi sound of the guns Such a unit would be of incalculabl value in promoting immediate treatment of the tru dysenteries, and the immediate return to the front lin of patients with granular proctitis

Note on Treatment

It is my impression that phthalylsulphathiazol suppositories (Cluer 1947) have a place, albeit small in controlling idiopathic granular proctitis It is tru that, since no infective agent has been incriminated, th use of an antibacterial drug is empyrical Plain coco butter suppositories are probably just as effective, and it is worth prescribing these, particularly in periods o quiescence Although severe secondary anæmia was no observed in this series it can develop (B N Brooke, personal communication) and would indicate iro therapy Probably the most valuable part of the treatment is reassurance

Summary

26 cases of idiopathic granular proctitis are reviewed.

The recognition of this syndrome is important, so that it can be clearly distinguished from the more serious conditions of which it may be a forerunner, a concomitant, or a sequel

I wish to thank Mr B N Brooke for his advice during the preparation of this article Seeing that war pensioners' medical documents have been used, it is fitting that acknowledgment should be made to the Ministry of Pensions and National Insurance for permission to use these records.

It lly deserves a volume to itself

There are other reasons for reading this book than an wish to recapture a taste of the purposeful energy of n years ago. It is a monument to many anonymous n whose efforts brought victory from near-defeat: tains many hints and suggestions which deserve her inquiry in these quieter days.

Operative Orthopedic Clinics

LEWIS COZEN M.D F.A.C.S assistant professor of orthopedic surgery, College of Medical Evangelists Los Angeles ALVIN BROOKWAY M.D chief of staff Orthopedic Hospital Los Angeles; in collaboration with PAUL E MCMASTER, M.D., F.A.C.S clinical professor of orthopedic surgery University of California. Philadelphia: J B Lippincott London: Pitman Medical Publishing Company 1955 Pp 329 80s

IN their preface the authors say: An attempt has been made figuratively to allow the reader to take his place in the operating room of two busy orthopedic services. After the dictated report, the reader will find some remarks similar to the verbal comment the surgeon might make during and after the actual surgery' And later: 'Had the operative reports been dictated more carefully a more lucid picture of the operation would be present in many instances They do not pretend to cover all orthopædic operations, and their choice appears rather haphazard On the whole the descriptions of procedures are clear enough, though—with the method they use—there is necessarily much repetition. The main interest however lies in the subsequent comments, which cover a wide field not always directly relevant to the operation under discussion Though it is extremely hard for the reader to get a balanced view of the indications for any particular procedure he will pick up many valuable tips on overcoming the difficulties that can arise during operation.

The book is largely an account of individual technique, and this of course may differ widely from our own. But it is not easy to believe that displacement of the patella is ever necessary for the removal of an external meniscus or that removal of one-third of the proximal phalanx is sufficient in Keller's operation The illustrations leave much to be desired some being pointless, and others positively misleading Technique can be better learnt, on the whole, from the standard textbooks on orthopædic operations but the surgeon with some experience behind him will find much to interest him.

Experimental Psychology

Revised edition ROBERT S WOODWORTH Columbia University HAROLD SCHLOSBERG Brown University London: Methuen 1954 Pp 948 £3 3s

IN the course of his long life—he was born in 1869—Professor Woodworth has rendered great services to psychology, as investigator and teacher among the most valued of his contributions has been his handbook of experimental psychology The historian of this subject, E G Boring said of Woodworth that he "came as near to being the general experimental psychologist as any important man ever did,' and the range of his activities and experience justifies this extreme statement Allied with his exceptional gift for lucid exposition it enabled him to bring out a book of remarkably catholic completeness within its declared scope. The first edition appeared in 1938, after eight years of determined work in preparing it In 1949 Professor Woodworth and his collaborator undertook the present thoroughgoing revision The book contains more material than before but is not bulkier Historical surveys have been greatly reduced and some chapters (e.g., on feeling and experimental æsthetics) have been dropped The magnitude of the authors task may be gauged from the size of the bibliography—about 2480 titles, half of which had not been used for the first edition The chapters on emotion and on learning have been reorganised, in accordance with current development in these fields.

This is not a handbook of psychology It largely omits, for example the field of individual differences, social psychology much of animal psychology, child development, and applied psychology the name of Freud does not appear in the bibliography nor Piaget nor MacDougall It is concerned only with experimental psychology, which is not the whole of psychology but the most solid and communicable part, and that which experimental biologists generally and physiologists in particular will find closest to their own scientific problems and habits of thought It is in its own field a masterly standard work

Virus and Rickettsial Diseases

2nd ed S P BEDSON, M.D, D SC, F R C P, F.R S, A W DOWNIE, D SC, M.D, F R S, F O MACCALLUM, B SC, M D, C H STUART HARRIS, M.D, F.R C.P London Edward Arnold 1955 Pp 407 30*s*

IT is no surprise that a second edition of this commendable work has been called for after five years Knowledge of viruses has increased so rapidly that there is much to be added or modified. Reviewing the first edition, we suggested that more would soon be needed about poliomyelitis following inoculations and about the Coxsackie viruses and the expected additions have been made, the Coxsackie viruses now having a chapter to themselves Naturally there is also a discussion about poliomyelitis vaccines, and it is very apposite There is a new section on virus multiplication, but the chapter on bacteriophages has been dropped Altogether the book is as up to date as could be hoped for there are references to cultivation of varicella and the viruses of acute respiratory disease, though not to Enders's recent work on measles

Weltraumstrahlung

Der heutige Stand der biologischen Erforschung J EUGSTER, Privat-Dozent, University of Zürich Berne and Stuttgart Hans Huber 1955 Pp 141 Sw Fr 26 00

THIS is an up-to-date review of the present state of knowledge of cosmic radiation, by an author who has made considerable contributions in this field

The book is divided into two main sections, the first being devoted to the physical properties of cosmic rays, and dealing in turn with heavy primary particles, star producing nucleon components, neutron components, electron showers, and the relative intensities of the components at various locations above and below the surface of the earth The emphasis is on the possible biological effects of the physical phenomena discussed

The second main section deals with methods of investigating the biological effects of cosmic rays Three methods enabling the investigator to determine which cells have been the targets of cosmic ray components are reviewed The first consists of placing a regular pattern of test objects in close proximity to two layers of nuclear emulsion, the second involves the injection of emulsion directly into the tissues under investigation, while the third relies on the photochemical action of incident radiation on certain dyes (e g, triphenyltetrazolium chloride) or enzymes (e g, ATPase) In a critical discussion of the results obtained by these methods, Dr Eugster emphasises particularly the importance of examining the effect of cosmic rays on individual cells rather than on whole tissues or animals

Two of many questions still requiring answers are whether exposure to heavy primary particles and to nuclear disintegrations can convert precancerous to malignant cells and whether induction or growth of spontaneous or chemically induced tumours may be influenced by maintenance in an environment of low radiation level There are more than 400 references.

Textbook of Gynæcology (4th ed London Heinemann Medical Books 1955 Pp 490 27*s* 6*d*)—Gynæcology, Mr J H Peel implies in the preface to his fourth edition, has stood reasonably still for the past five years—anyhow as far as medical students need be concerned. This has left him free to revise his text without major rearrangement, to include new theories about disorders of menstrual function, and to exclude syphilis, which is now so come down in the world as to claim no place in a textbook of gynæcology Dr E W H Shawcross has rewritten the section on X ray treatment, and a new set of drawings of the principal gynæcological operations, by Mr R N Lane, will be welcome to students

The Diabetic Life (15th ed London J & A Churchill. 1955 Pp 228 12*s* 6*d*)—Dr R D Lawrence's book has been a practical guide to the treatment of diabetes for thirty years. This edition includes advice on the use of the new insulins, and other fresh matter

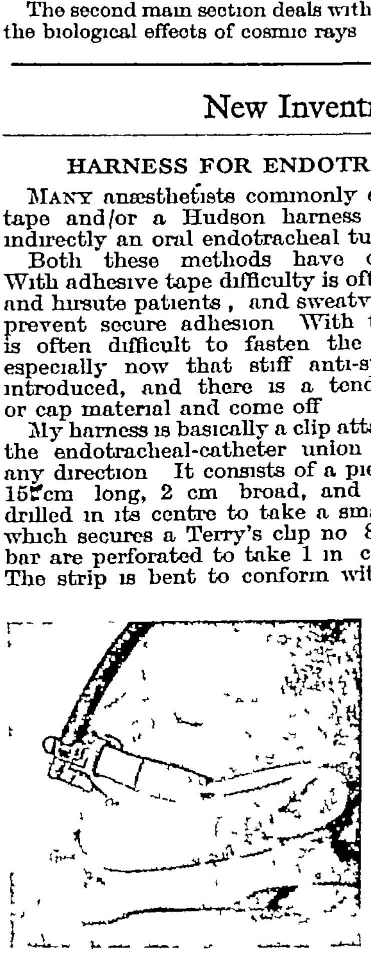
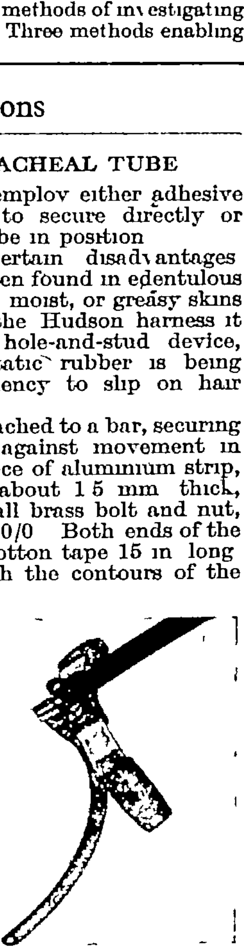
HARNESS FOR ENDOTRACHEAL TUBE

MANY anæsthetists commonly employ either adhesive tape and/or a Hudson harness to secure directly or indirectly an oral endotracheal tube in position

Both these methods have certain disadvantages With adhesive tape difficulty is often found in edentulous and hirsute patients, and sweaty, moist, or greasy skins prevent secure adhesion With the Hudson harness it is often difficult to fasten the hole-and-stud device, especially now that stiff anti-static rubber is being introduced, and there is a tendency to slip on hair or cap material and come off

My harness is basically a clip attached to a bar, securing the endotracheal-catheter union against movement in any direction It consists of a piece of aluminium strip, 15 cm long, 2 cm broad, and about 1 5 mm thick, drilled in its centre to take a small brass bolt and nut, which secures a Terry's clip no 80/0 Both ends of the bar are perforated to take 1 in cotton tape 15 in long The strip is bent to conform with the contours of the maxilla at the level of the upper lip The bar is padded at either end with rubber guards 4 5 cm long covering the junction of the bar with the cotton tape The bolt head in the middle of the bar is padded on the facial side by 2 cm of 5 mm. thick sponge rubber secured by rubber bands 1 cm wide at either end The jaws of the Terry's clip are covered by 1 cm of anti static rubber on each





After the introduction of an oral cuffed or uncuffed tube the clip is placed in position beneath the nose, and the endotracheal-catheter union is pushed into place between the jaws of the clip The rubber-tubing connection to the anæsthetic-gas supply is then attached without any further securing device One tape is passed behind the neck to tie with the other at the side of the jaw In practice this gives absolute security against all untoward sudden movements often experienced in moving the patient into position in the theatre, and in giving controlled respiration It is in such manœuvres that small movements of the endotracheal tube can give rise to troublesome "bucking" in a lightly anæsthetised patient

The harness has been designed with the Waters to-and fro apparatus in mind but can be used with the usual heavy corrugated connecting tubing This size clip (80/0) will hold Rowbotham's union piece, Magill's nasal, oral, and suction T-pieces, Gillespie's, Cobb's suction union, and Ayres T-piece Nosworthy's middle-size endotracheal unions are also taken, but the larger and more angular unions of this type are less securely held

This clip has been used for securing oral endotracheal tubes in more than 100 patients aged 2–75 years, and requires no bending or manipulation once it has been moulded to the contours of the average maxilla It will also withstand repeated boiling and, provided that the rubber tubing delivering the anæsthetic gases is anti static, does not require further earthing

The harness is obtainable from Medical & Industrial Equipment Ltd, London.

THE LANCET

LONDON　SATURDAY JUNE 18 1955

By any Other Name

The beguiling euphemism "observer variability" has now been applied to the mistakes in interpreting radiographs It is quite clear that a single observer attempting to pick out cases of pulmonary tuberculosis from a largely normal population is likely to overlook about a quarter of the abnormal films This proportion has been remarkably constant in repeated trials in several countries, and any variation is more likely to be due to variation in the composition of the population (and especially to the number of difficult borderline cases) than to any difference in skill. Tests of observer error reveal, in addition to the frank "misses," a great lack of consistency An observer is likely to disagree with his colleagues concerning one in five of the positive cases, though he is a little more consistent with himself, when given the opportunity—for instance, in assessing progress—he swings from 'better' to 'worse" at second examination of a film in 7% of cases [1]

The reasons for this surprising state of affairs are not clear but failure to detect very slight changes is not the only factor, for it is not only the minimal cases that are missed Groth Petersen and Møller [2] have shown that of the cases missed on a single reading 86% were sputum positive, 35% were of bilateral disease and in 15% there were cavities. Nor are the "misses" necessarily lesions difficult to spot given a second chance, the observer may immediately detect the abnormality and be amazed that he ever overlooked it It also seems unlikely that the speed of working is an important factor for though test material is sometimes examined rather hurriedly abnormality is usually quickly spotted and prolonged searching does not yield many more cases—though it rapidly increases fatigue Perhaps boredom and the hypnotic effect of the repeated normal are more important Opinion can easily become biased in favour of the predominant, after reading many more or less orm films the observer becomes less inclined to ark on the slightly exceptional Accuracy might ease if test films were read in small batches of twenty to twenty five once or twice a day, an eriment on these lines would be valuable It has n suggested [3] that the conditions of the tests are ly responsible for some of the inaccuracies and onsistencies they reveal the observer has a sense of m and is forced to reach decisions not made in tine practice. Thus the tests probably present the ture at its very blackest Nevertheless attempts test observers without their knowing it have not supported the soothing notion that the observer is much less fallible in ordinary routine work.

One of the more surprising conclusions from these tests is that small films, properly used, can be as reliable for the detection of tuberculosis as the conventional full sized films—but only if they are interpreted independently by two readers Fortunately small films are easy to handle and can be readily viewed in special illuminators or projectors in batches of 50–100 A year ago [3] we suggested that the simplest and most effective way of increasing the efficacy of chest radiography surveys would be by dual reading This contention is supported by Clayson et al, [4] and by Dr Stradling and Dr Johnston whose article appears on an earlier page of this issue Clayson et al set out to determine whether 70 mm. photofluorography is a safe and proper method for chest-clinic work By an ingenious and thorough analysis of their results much more was brought to light They found, firstly, that for the detection of tuberculosis independent dual reading of 70 mm film can be as effective as single reading of large films Secondly, they found that accuracy and consistency improved when simple classifications were used, and were greatest when only "clinically significant" cases were being sought (An attempt to determine which films showed "active lesions" produced the greatest variability underlining the absurdity of trying to do this by radiography alone) Thirdly, they determined the most reliable method of case-finding Results were best when the small films were used solely to select cases needing further investigation. When the films had been read independently by two readers, all the cases questioned by each reader were recalled The large films then taken were also read by both readers independently Even under these rather exacting conditions the cases of active disease that were missed and were subsequently detected amounted to an additional 20% or so

Stradling and Johnston report their experience with 70-mm film at the Hammersmith Chest Clinic Well aware of the dangers of single observations, they make independent dual reading the rule, and they confirm the increased yield of cases This double-checking inevitably increases considerably the number of patients recalled for further investigation most of whom will prove to be free from disease In an attempt to avoid some of the fruitless increase, they took, in every case, two films—an ordinary postero anterior projection and an anteroposterior lordotic projection. The results seem very satisfactory the number of recalls dropped from 111 to 76 for one reader from 280 to 132 for the other, and from 342 to 185 for both together This is a most important observation. Small films can compete in accuracy with large films only if dual reading is adopted, but the consequent increase in recall rate (which is sometimes almost doubled) has been regarded by many as an overwhelming objection to this method —particularly when applied to industrial workers at the factory or pit during working hours when the temporary withdrawal of a single person may put a whole team out of action. But is dual reading of two films in every case more trouble than it is worth? Would it be more economical, easier, and safer to use

large films from the start? The real advantage of miniature photofluorography is that it can deal with very large numbers, but for the examination of smaller numbers its advantages are less obvious Certainly those particularly exposed to risk of infection—such as tuberculosis contacts, nurses, or medical students—should not be given clean bills of health on the single reading of a miniature film, and there is much to be said for using large films—read twice—to examine such smaller groups, who for one reason or another are already preselected So far photofluorography has been found reliable only for the detection of tuberculosis, and this method is not necessarily equally valid for detecting shadows of a different quality—for instance, those of pneumoconiosis[5] In the early stages of a dust disease the lesions are smaller and softer, and are best seen towards the periphery of the lungs, where in miniature films the definition may be impaired by spherical aberration. The suitability of small films for this purpose can be proved only by experiment, but this would be no simple matter, since numbers would have to be large and the investigation most carefully planned to make full allowance for the effect of observer error

Whatever the purpose of the examination, and whatever the size of the film, it is now apparent that the radiograph should preferably be read by two observers

Biochemical Disturbance in Hepatic Coma

THE association of mental disturbance with hepatic disease has been recognised since the days of GALEN, but even now the underlying mechanism is far from clear The term "cholæmia," introduced by LEYDEN[6] in 1866, by analogy with uræmia, implies that the essential fault is in excretion This hypothesis has had to be abandoned owing to the absence of "cholæmia" in cases of complete biliary obstruction and the failure to incriminate any of the known constituents of the bile The known functions of the liver now amount to several hundred (and doubtless many more remain to be discovered), so it is hardly surprising that the disturbances responsible for the cerebral disorder have not been easily elucidated All recent work suggests that the cause is either a breakdown in the detoxicating function of the liver or liberation of a toxic by-product of its disordered metabolism

In view of the essential rôle of the liver in carbohydrate metabolism, and the death in hypoglycæmia of laboratory animals after hepatectomy, hypoglycæmia might reasonably be expected to be a conspicuous feature of hepatic failure Yet with few exceptions the blood-sugar levels of patients in hepatic coma are within the normal range Disturbances of blood electrolytes resulting from the hepatic disorder and the massive intravenous glucose injections with which it is often treated are a largely avoidable, but relatively uncommon, cause of cerebral symptoms WALSHE'S[7] study of the amino-acids in the blood, urine, and cerebrospinal fluid of patients in coma and precoma revealed more consistent abnormalities, of which a rise in the level of glutamine, and sometimes also of glutamic acid, was the most striking

On the basis of these findings WALSHE "suggeste tentatively that changes in the amino acid pattern of the body fluids are capable of producing varyin neurological syndromes," including hepatic coma A few years earlier it had been found that administra tion of ammonium chloride to patients with cirrhosi sometimes induced neurological complications[8], an it seemed that the raised glutamine level found b WALSHE in the cerebrospinal fluid might resul from a detoxication mechanism by which the highl toxic ammonium radicle was removed—namel by combination with glutamic acid to form the amid glutamine According to this view, cerebral symptom associated with hepatic disease are the result o ammonia intoxication The recent findings o Dr SHERLOCK and her associates[9] confirm th correlation between the blood-ammonium level and the appearance of cerebral symptoms These workers point out that such a rise can result either from failure of the injured liver to deal with the ammonia arriving via the portal vein or from by-passing of the liver by the collateral circulation provided by portal-systemic anastomoses They emphasise that since neurological changes can occur without a significantly raised blood-ammonium level, and identical changes can be precipitated by orally administered methionine, the relation of blood-ammonium level to hepati coma may be similar to that of the blood urea level to uræmia—i e, a correlation exists but it is not causal This hypothesis attributing the cerebral symptoms to ammonia intoxication has led to the use of large doses of glutamic acid in the treatment of hepatic coma[10] In a small number of patients with hepatic cirrhosis the response to this treatment was quite dramatic But the results are inconsistent and unpredictable, and in patients with massive necros they have been uniformly disappointing Dr WALSHE in a paper published this week on p 1235, confirm these experiences He emphasises that the stat of the intracellular mechanism dealing with exces ammonia is more important than the ammonium level in the blood Thus cerebral disturbance could arise from an intracellular defect of this mechanism in the presence of a normal blood-ammonium level and conversely levels usually regarded as toxi could be tolerated in the presence of enhanced intra cellular detoxication BESSMAN and BESSMAN[11] have shown, by a study of the arteriovenous differenc of blood-ammonium, that there is a considerabl peripheral utilisation of ammonia, presumably in muscle Levels of ammonia in systemic venous blood may therefore give no reliable indication of the level in the arterial blood reaching the brain, and this could account for some of the discrepancies recorded by SHERLOCK BESSMAN and BESSMAN have also shown that in the presence of a raised blood ammonium level there is considerable intracerebral utilisation of ammonia with a corresponding increase in the cerebral arteriovenous difference Such utilisation might be due to synthesis of glutamine, but this requires adenosine triphosphate and would result in an enhanced oxygen uptake, whereas the available evidence shows that in coma and precoma uptake of oxygen by the brain is depressed. BESSMAN and BRADLEY therefore suggest that the main reaction consuming ammonia is the conversion by reductive amination of α ketoglutaric acid to glutamic acid. This could result in the removal of α ketoglutarate, an essential member of the Krebs cycle, and consequent reduction of the oxidative metabolism of all those metabolites with which this cycle normally deals—a disturbance that would explain the rise in blood pyruvate and glutamate.

The metabolic activities of the liver are so complex that the mental disturbances in patients with hepatic disease would hardly be expected to depend always on the same biochemical disorder. The presence of "fœtor hepaticus" in patients gravely ill with disease of the liver directs attention to toxic metabolites other than ammonia. Professor CHALLENGER and Dr WALSHE report (also in this issue) the isolation from the urine of such a patient of methyl mercaptan and dimethyl disulphide. These products are derived from methionine by chemical reactions known to occur in vivo. The greatly increased blood level of methionine in hepatic disease—probably the result of impaired capacity of the injured liver to handle this amino acid—presumably favours the abnormal metabolic pathway that leads to these odoriferous sulphur compounds. That they are toxic seems likely. Other possible products of disordered methionine metabolism arising from partial oxidation, such as the sulphoxide and the sulphone, may contribute to the clinical picture.

Recent work on the mechanism of hepatic coma thus incriminates ammonia and various sulphur-containing by-products of disordered methionine metabolism. That these comprise by no means all the complex biochemical machinery that relates hepatic to cerebral dysfunction is almost certain. Since there is probably no single cause of hepatic coma would it not, as WALSHE suggests, be advisable to refer to "the hepatic comas"?

An Incomplete Reform

UNWITTINGLY King GEORGE III did much to take the stigma of moral guilt from insanity. The effects on public opinion and on lunacy reform of his first attack of mental illness were (Dr KATHLEEN JONES writes[1]) intangible but real. On his recovery in 1789

the people were warmly sympathetic; there was for him none of the condemnation then usually accorded to the insane.

> "Nobody suggested that the King was being punished by heaven for his sins; nobody regarded him as being possessed by the Devil; insanity had become a respectable malady—one which might happen to anybody; and, which is even more important, one which was susceptible to treatment and capable of cure."

Not that the treatment accorded to the King was in any way more enlightened than that suffered by other mental patients at the time; he was purged, beaten, starved, and kept in bonds like the rest. But his illness marked a turning point; for, though there had already been some stirrings of concern about the fate of the insane, little had been achieved before that time.

In the early part of the 18th century the medieval conception of charity as a duty every man owed to his neighbour was dying out, and there was no corporate sense of responsibility to take its place. The insane were not regarded as any kind of separate group; if mental illness brought them to penury they came under the poor law; if it caused them to commit a crime they were judged under the penal code; if they wandered without means of support they came under the vagrancy laws. Bethlem was the only institution of public standing which dealt with the mentally abnormal; and Bethlem—"Bedlam"—was passing through its terrible years. The rich might be kept at home or sent to small evilly run madhouses which offered a pledge of absolute secrecy; the poor were kept in such holes and dark corners as their family chose, or sent to a workhouse or prison. Many still fell under suspicion of witchcraft; and, though the penal laws against witchcraft were repealed in 1736, there were still plenty of people in far villages to try by ordeal insane people suspected of dealings with the devil. Standards of professional training in medicine were miserably low, and treatment was directed to weakening the insane patient by the systematic use of purges and emetics, by bloodletting, blistering, and cautery. The clergy held that human misery was the result of personal sin, while philosophers believed in "natural law" and took the world as they found it, lunatics and all. Pauperism from other causes than insanity was increasing; and the name "workhouse" carried with it, as an official publication of 1732 noted, "an idea of Correction and Punishment." In 1789, when GEORGE III journeyed to Weymouth for his convalescence, there were in workhouses—where punishments for not working or for "mischievous conduct" included solitary confinement in a dark room and deprivation of food—some 4000–5000 psychotic or mentally defective people. Many others were in prisons or bridewells.

Yet as early as 1742 a select committee set up to revise the vagrancy laws had paused to consider dangerous lunatics; and the Act which resulted from their recommendations did at least order that the warrant of two or more justices of the peace should be required for their detention instead of only one justice as for any other vagrant. By 1763 some facts about conditions in private madhouses had become public, and had led to a movement to get statutory supervision of such places. A select committee was appointed; but a Bill to control the abuses was not introduced till ten years later, and then it was rejected by the Lords. An Act for Regulating Private Madhouses was indeed passed in 1774; but was so weak and ineffectual that it produced little change in the contemporary scene. Nevertheless, Dr JONES points out, it did establish five important principles: that private institutions run for profit should be licensed by a public authority; that the reception into them of people alleged to be insane should be notified; that commissioners whose method of appointment should be prescribed by Parliament should visit them; that inspection should ensure that those wrongfully detained were released and those rightly detained should be humanely treated; and that they should be supervised by doctors. It was many years before effective legislation converted these principles into practice. Dr JONES notes—and it is a thing true of every age—that the reformers themselves were not entirely aware, in these early days, of what they wished to achieve Perhaps, too, they were rather easily satisfied

---

[1] Lunacy, Law and Conscience. By Mrs KATHLEEN JONES, PH.D. The International Library of Sociology and Social Reconstruction. London: Routledge & Kegan Paul. 1955. Pp. 231. 21s.

Much was being done outside Parliament Hospitals were being set up—St Luke's, London, in 1751, the Lunatic Hospital at Manchester in 1763, and the Retreat at York in 1792 In the first and last of these, gentle measures of treatment and occupation were advocated, and the Manchester Lunatic Hospital dealt more humanely with patients than was common at the time But the founding of asylums on a national scale began only with the County Asylums Act of 1808, which in turn followed the report of a select committee appointed in 1807 Amending Acts in 1811, 1815, and 1819 dealt with questions of admission, certification, and discharge of patients These took the responsibility for the admission of patients from the overseers of workhouses and placed it in the hands of magistrates, " thus weakening the connection of the county asylums with the Poor Law authorities "

Meanwhile Samuel Tuke had published, in 1813, his *Description of the Retreat*, setting out the " moral " management of the insane as practised there—management, that is, by gentle treatment and social activities Tuke, moreover, as a member of the Society of Friends, believed in the integrating influence of religion His patients were given no reason for feeling that their mental disorder cut them off from ordinary interests and activities The book was widely read, and when another select committee was set up, in 1815, public opinion was strongly with the reformers The committee found both law and practice in chaos At one end of the scale was the humanity of the Retreat, at the other the unspeakable barbarities of the private madhouses They published evidence of appalling conditions, dreadful neglect, and much cruelty Yet Bills to reform the private madhouses, introduced in 1816, 1817, and 1819, were all, after passing the Commons, rejected by the Lords, the main and most telling opponent being Lord Eldon, the Lord Chancellor After the third defeat the little band of reformers began to disintegrate the mentally ill had to wait on, year after year, for another champion

They found him in 1827, when a new select committee was appointed with Lord Ashley (afterwards Earl of Shaftesbury) among its members The committee introduced two Bills, both of which went through without difficulty the new County Asylums Act required visiting justices to send annual returns of admissions, discharges, and deaths to the Home Secretary, and the Madhouse Act placed the power of inspecting the Metropolitan houses in the hands of a statutory authority The 15 commissioners appointed under it were to visit without warning, and they had power to recommend that licences should be revoked The Act also required that a certificate for confinement of any patient should carry the signature of two doctors, as it does today An exception was made in the case of pauper patients, for whom the signature of one doctor, the parish overseer, and the incumbent, or of two justices, sufficed The new commissioners, who included Lord Ashley, worked so well that two years wrought a most striking change for the better in the Metropolitan madhouses As the years passed, the commissioners extended their interests they began to inquire into the characters and conduct of attendants and nurses, listened to patients' grievances and investigated them, and tried liberating recovered patients on trial In 1842 an Act was passed empowering the commissioners to pay a visit to every asylum and madhouse in the country The report on the first tour of inspection—" Ashley's report," Dr Jones says it may fairly be called—was published in 1844 and was the basis of the Lunatics Act, 1845 This gave the lunacy commissioners power to visit not merely the Metropolitan asylums and madhouses, but all county asylums and hospitals for the insane, and any other institution in which the insane might be found Bethlem—a much reformed Bethlem by this time—was deliberately excluded from such supervision. The Act also provided new methods of certification which decreased the risks of wrongful detention, and required better record-keeping Ashley believed in the value of documents as a safeguard against irregular practice The apathy and opposition which had defeated earlier Bills had disappeared the House of Commons was strongly in favour, and such opposition as there was came almost entirely from people who thought the Act did not go far enough

This is as far as Dr Jones's review of English legislation for the mentally ill takes us, but in an epilogue she reminds us of the landmarks of the last hundred years—the Lunacy (Consolidation) Act of 1890 (most of its provisions still apply to certified patients), the mental deficiency legislation of 1913–27, the Mental Treatment Act, 1930, and the National Health Service Act, 1946 Nor is the task of reformers in any sense finished A Royal Commission, headed by Lord Percy of Newcastle, set up last year, is considering the extent to which it is now, or should be made, statutorily possible for mentally ill or mentally defective people to be treated as voluntary patients without certification Northern Ireland[2] has already shown us that, by appropriate legislation certification, with all its attendant deprivations and legal disabilities, can be very largely avoided

The story of the change from gross superstitition and carelessness to a sense of responsibility for the mentally sick can be paralleled by several other developments in our social history over the past two hundred years Those who have read Sir David Henderson's Morison lecture,[3] however, will be struck again by the resemblance he sees between our attitude to the mentally ill and our attitude to " the behaviour and thought disorders which are indicative of abnormality and crime " Both the mentally sick and the socially undesirable are capable of rousing ugly responses in the rest of us we find it hard to keep in mind that an antisocial or otherwise troublesome person still counts as one, and not some negligible fraction Over the past two hundred years our response to the mentally sick has become progressively healthier and more mature, our reaction to criminals, too, has been maturing, though at a slower rate—being more primitive, as yet, by as much perhaps as a hundred years Of our progress in the mental field Dr Jones says " as we reach the point where history shades into present policy and future aspirations, we may derive confidence, if not complacency, from the achievements of the past two hundred years " Perhaps the same may be cautiously said of penal reform

Annotations

REST AND ACTIVITY IN ACUTE NEPHRITIS

Akerrén and Lindgren[1] have been investigating the important question of how long strict bed rest is necessary for patients with acute hæmorrhagic nephritis They define the régime in the Children's Hospital at Gothenburg as rest in bed not only until possible 'general nephritic symptoms' such as increased blood pressure œdema, or raised N.P.N have disappeared but *also until the urinary findings* have returned to normal or practically normal. In questioning the need for this expensive routine, they were encouraged by finding that Czerny of Prague, had recorded in his memoirs in 1939 that children with acute nephritis who played in the streets recovered just as rapidly and completely as those who were made to rest From 1946 onwards Akerrén and Lindgren have treated alternate patients with (*a*) strict bed rest and (*b*) mobilisation as soon as macroscopic hæmaturia had disappeared Patients with recurrent attacks of hæmaturia associated with acute infection were later excluded, leaving 57 patients of whom 20 had been allowed to get up as soon as overt hæmaturia had disappeared. They found no noteworthy difference between the two groups Albuminuria and microscopic hæmaturia and increased sedimentation rate were not more persistent in the "up-and-about" group Tests of renal function gave similar results in the two groups and the length of time spent in hospital was rather shorter in the ambulant group Akerrén and Lindgren cite similar observations by Frisk and Klackenberg[2] and by Rudebeck.[3]

Early ambulation in acute nephritis, especially if it leads to earlier discharge from hospital is clearly of advantage to the community but it is not quite certain that thereby the patient is running no increased risk of chronic illness The present series was limited to children who do rather better than adults. Moreover there is some evidence that the attacks studied were very mild for of the 57 patients only 2 had tangible œdema and only 3 had hypertension Again there is no information about the delayed incidence of chronic nephritis. Acute type I nephritis though the ultimate prognosis is relatively good,[4] may be complicated by cardiac failure[5] by encephalopathy and by pulmonary œdema all of which require bed rest and some of which may outlast macroscopic hæmaturia. On the other hand no-one would want to keep patients with acute nephritis in bed until the last traces of albumin had disappeared, which might be at the Greek kalends A fall in blood pressure and a rise in urine volume—which may be abrupt[6] —are probably better signals for allowing the patient up than the disappearance of gross hæmaturia

RADIOGRAPHY OF THE COLON

RADIOGRAPHY can contribute much to the diagnosis of lesions of the colon especially those beyond the range of the sigmoidoscope But the radiologist often finds that the loops of the colon overlap and obscure each other so that inspection of a suspected area is very difficult and he may also be impeded by spasm or actual obstruction of the colon during the barium-enema examination The colon must be completely outlined in the filled state and all its tortuosities displayed then after the patient has evacuated his bowel it is highly desirable that enough of the barium shall remain to outline the mucosal pattern

It is not always easy to display the mucosal pattern of the colon Fischer[1] advocated for this purpose insufflation with air and Maingot et al[2] the use of thorium-oxide suspensions in place of barium sulphate Rigler[3] suggested in the early thirties that tannic acid should be added to the barium suspension but this method was widely adopted only in the late forties after Hamilton[4] and others had established a claim for it McLaren et al[5] have carried the search for an effective technique a stage further by using 'Veripaque' (dihydroxyphenylisatin) with a barium-sulphate suspension in which the particles are below 0·5 µ in size Veripaque is a colon stimulant, promoting rapid and complete evacuation and the colon can be observed radiographically as evacuation takes place through the enema tube after the colon has been completely filled McLaren et al say that with this substance the rate of colonic movements is suitable for accurate observation the contractions appear normal in character but increased in speed and vigour Apparently the increased rate of segmental and mass contractions is not associated with as much colic as may occur when tannic acid is used and McLaren et al claim that there are no contra-indications to the use of veripaque. From their experience they conclude that it aids study of structural detail and functional activity, and eases, for example, diagnosis of neoplasm and assessment of stenosis in regional ileitis involving the colon

DANGEROUS COTS

THREE children have died and one has narrowly escaped death as a result of accidents in their cots All the cots had bars close enough together to prevent the children from getting their heads between them and all the accidents were of the same type: the children slipped between the bars feet first and since their heads would not pass through, the weight of their bodies pulled their faces into the bedding and—except for the one rescued in time—they were smothered. In recent years the British Standards Institution (B.S.I.) have issued three standards for hospital and domestic cots, and two of these—issued in 1950 and 1951—recommended that cot bars in hospital metal cots should be 3–3¹/₂ in apart and those in domestic wooden cots not more than 3³/₄ in. apart. (Metal bars are less rigid than flat wooden bars, and hence may become slightly bent) The Ministry of Health and the Home Office were represented on the committees passing these standards—to which they have hitherto given their support In view of these accidents however they have felt obliged to consider the possibility that a standard devised to eliminate one type of accident may contribute to another type

In a Ministry of Health bulletin Dr Rachel Elliott and Mr W H Hammond[6] report that before the British Standards Institution was approached about altering these standards, two large health authorities (the London County Council and Birmingham County Borough Council) and a London pædiatrician were asked to collect measurements of babies and young children aged 6 months to 3 years Anteroposterior chest and pelvic measurements and head measurements made on some 600 children in L.C.C nurseries 600 in Birmingham nurseries and nearly 400 in London hospitals made it clear that a large proportion of children aged 18 months, greater numbers of younger children and even some 3 year-olds would be able to get their hips through a 3¹/₂ in space

The chest depth would prevent all but 1% of year old babies and 5% of 6-month babies from being able to squeeze through far enough to hang by the head, but the Ministry of Health rightly felt that in view of these findings the B S I should be asked to reconsider the standards The committee dealing with hospital cots did so, and—with full agreement between the medical representatives and the manufacturers—issued a new standard recommending bar spacing of $2^3/_4$–3 in, with an upward tolerance of $^1/_{16}$ in But unfortunately, the manufacturers of domestic wooden cots have not so far been persuaded to alter the bar spacing recommended in the existing standard The possibility of devising some kind of lattice work or mesh, which would get rid altogether of the need for bars and their hazards, does not seem to have been considered

The Folding Furniture Manufacturers' Association, whose members make 99% of babies' cots, claim that they have always put safety in the foreground of their policy, and that they have a record of fifty years of manufacture, at a rate exceeding 100,000 cots per annum, without a single fatal accident This is a good record, which they must surely be the last to wish to see broken It is therefore strange to find them arguing that the risk is only theoretical, depending upon the children being sufficiently emaciated to wriggle through the bars, and "able to contort themselves into the necessary sideways position, and upon the flesh over the buttocks, which was excluded from the measurements, not preventing passage" The 3 in specification, they say (taking a flight of their own into the realms of theory), "will lead to innumerable accidents such as fractures of arms, legs, &c" They add that the risk described by the Ministry of Health is "so remote as to be more than outweighed in terms of safety measurements", and that they would welcome an independent public inquiry

It is difficult to see how any further inquiry would help This is not a question of theory at all—of what kind of baby by what contortions could bring himself to an untimely end in this way It is a question of fact three children have already died from accidents in cots with bars so spaced that their bodies but not their heads could pass between them Surely the Folding Furniture Manufacturers' Association do not wish to wait until a child dies in this way in one of their own cots? Surely they would rather stand by their own policy and prevent even the possibility of another such disaster?

PERONEAL SPASTIC FLAT-FOOT

THE syndrome of spastic flat foot, with an eversion deformity, pain in the foot, and tightness of the tendons on the outer side, has still not been fully explained Bony abnormalities in this region contribute to the disorder[1 2], and in 17 affected feet Harris and Beath[3] found 15 abnormal bars, either between the calcaneum and navicular or between the talus and navicular With the special radiographic projections which are necessary to demonstrate the bar it became possible to separate those cases with primary bone defects, which were probably congenital, from those with arthritis in the subtaloid joint

Spastic flat-foot is almost exclusively confined to adolescents (the Canadian Army foot survey gives an incidence of 2%) and is much commoner in the male than in the female The height of the long arch is often unchanged, and the peroneal muscles, although prominent, may not be in spasm but merely show adaptive shortening Possibly spasm, when present, is due to an irritative focus in the subtaloid joint, while true shortening occurs in the presence of a bony deformity There is some evidence[4] that the everted position is the position of rest for the subtaloid joint This suggests that treatment directed towards the muscles, or towards correction of the everted position, is misconceived Tenotomy of the peronei, or division of their nerve supply, provides only temporary relief, since other muscles continue to produce the deformity Blockley[5] has shown that manipulation and immobilisation in plaster in the corrected position for three months also gives relief, but at the end of two years few patients were noticeably improved

In the treatment of patients with symptoms associated with bony bars, fusion of the subtaloid and talonavicular joints seems to be justified, although Webster and Roberts[6] have suggested that in young patients without arthritis a bar may be resected Only in the absence of a bony abnormality does conservative treatment offer a reasonable prospect of success

BIRTHDAY HONOURS

IT is a pleasure to record the high distinctions conferred on Sir Horace Evans and Sir John Charles for two kinds of service to the Crown, and the additional honour given to Sir Alexander Macgregor, whose work for Glasgow has continued since he ceased to be medical officer of health and became chairman of the Western Regional Hospital Board Of the new knights Mr Geoffrey Keynes, of St Bartholomew's Hospital, has contrived to be both man of letters and man of action as a surgeon, a scholar, and a person, he has long since been accorded knighthood in the minds of his fellows Next year he will be visiting Canada and Africa as a Sims Commonwealth travelling professor—an office held in 1952–53 by one of the thre new Australian knights, Prof H R Dew of Sydney, whose scientific reputation was first gained by his studies of hydatid disease and malignant disease of the testis Mr A E Coates, of Melbourne, is likewise a surgical teacher, with special experience of vascular surgery and with a record of war service extending from Gallipoli to Japanese prison camps, while Dr D R W Cowan consulting physician to the Royal Adelaide Hospital, is an authority on tuberculosis These are but a few of the notable names appearing in the list which we publish on p 1266—a list impressive once again in the immense range, both geographical and professional, of the valuable medical work it brings momentarily into view

THE YOUNG LONG-STAY PATIENT IN HOSPITAL

M. U. SHARP
M.A. Camb
MEMBER OF ASSOCIATION OF GENERAL AND FAMILY CASE WORKERS

At the request of the South East Metropolitan Regional Hospital Board, an investigation was made during 1953-54 into the position of young long-stay patients in hospitals in south-east London and the counties of Kent and East Sussex. The purpose was to discover how many such patients there were, and whether the hospital arrangements, so far as their welfare or social life was concerned, were adequate and satisfactory. The age range taken was 15–45 years inclusive, and the only illnesses excluded were pulmonary tuberculosis, carcinoma, epilepsy, blindness, mental defect, and psychosis.

INVESTIGATION

Thirty hospitals reported having in all a total of 96 patients (47 men and 49 women).

Of these, 17 (6 men and 11 women) were in acute wards, but only 13 were undergoing treatment; 31 (23 men and 8 women) were in wards for young chronic patients; and the remaining 48 (18 men and 30 women) were in wards for elderly chronic patients, where 3 of them were receiving treatment.

Of the 17 patients in acute wards, 13 were correctly placed according to their needs: 5 in the Chailey Heritage Craft School, 4 cases of poliomyelitis in appropriate hospitals, and 4 others undergoing active long-term treatment. The remaining 4 were untreatable.

Four hospitals, between them, have been able to accumulate [illegible] young patients together, often by exchanging them with elderly patients. This left 48 cases in wards for the elderly chronic sick, and 4 other cases in acute wards not receiving treatment, who could be regarded as being unsatisfactorily placed.

Most of the 96 patients have been in chronic sick wards for three years or more, 4 men and 1 woman having been in for over ten years each. No less than [illegible] of the patients (32 men and 37 women) fall into the age-groups 35–45 years; 12 (9 men and 3 women) were aged 15–24; and 15 (6 men and 9 women) were aged 25–34; 58 of the 96 cases (60%) suffered from diseases of the nervous system, of which disseminated sclerosis was the commonest, with 12 men and 15 women. Diseases of the bones and joints and muscles accounted for 13 cases, infective and parasitic diseases for 11, and congenital malformations for 7.

PROPOSED DISPOSAL

There were 52 young patients for whom more satisfactory arrangements could be made. No immediate change could be offered, but attempts were made to discover what their own wishes were. It was found that 24 (8 men and 16 women) would like to be moved, while 21 (12 men and 9 women) would prefer to remain where they were. A further 4 women were in any case too ill for transfer, and 3 women were undergoing treatment in chronic wards for the elderly.

The immediate need is thus to find some happy solution for the 24 patients who wish to be moved; but it would be wrong to write off the others as happy and satisfied with their surroundings. The reasons given for not wishing to be moved were: nearness to relatives (10); a preference for the known to the unknown (9); a wish not to lose the friendship of the patient in the next bed (2). This does not necessarily imply that the best is being done for these patients, or that they would not have chosen to go elsewhere had a more suitable offer been made at the time of admission.

The solution for those who wish for a move does not lie in providing wards for 8 men and 16 women: the problem is far more complex. The 8 men are at present in eight hospitals and the 16 women are in ten hospitals scattered throughout the region. In only two instances are any 2 of the women in the same ward; for some are light and some are heavy cases and they are distributed accordingly. Again, patients who wish to leave their present surroundings do not all wish to be far removed from their home district. It must also be borne in mind that patients in the early stages of disseminated sclerosis would find it very depressing to be close beside those in the advanced stages. It would be easy, too, for someone with a difficult or abusive temperament to wreck the happy atmosphere of a ward. Care must therefore be taken in the initial stages of building up any unit for the young.

But it would not be right to emphasise the difficulties without also stressing the urgent need for better provisions for these young patients. Two case histories may speak for all.

Case 1.—A spastic of 38, severely handicapped in his legs but with use of his hands and very alert mentally. His father was a professional man, and he was used to life in a comfortable home until he was placed in a sheltered workshop. He was later transferred to the chronic ward, to be the only young one among the old men, with no outlet for his intellectual interests, and only handicrafts with which to occupy his time.

Case 2.—A woman of 25, bedfast with disseminated sclerosis, who, because of the degree of nursing care required, is placed in the ward with the very elderly and senile patients. Her hands are too shaky to do more than a little knitting, and her sight is too much affected to make reading possible. She is beset with worries about her husband and small boy at home, and has nothing to take her mind off her troubles as she gazes idly round the dreary ward full of those nearing their journey's end.

THE SCHOOL-LEAVER

The Ministries of Health and of Education combine to offer the severely handicapped child nursing, and schooling in a suitable environment; but what provision is there for him if further institutional care is essential, or if his home is inadequate to deal with his needs when he has to leave at the age of 16? Is the chronic ward the only answer which the Welfare State can give?

Case 3.—A boy was at grammar school when he caught poliomyelitis; it left him paralysed in all limbs, with the exception of his right foot, tips of fingers, neck and head muscles. Much effort was necessary before he would face life again and find in it some compensation for all he had lost. He can write now with a pen in his mouth and is learning remote-control typing, and it is possible that he may be able to sit for part of his General Certificate of Education shortly. But what of his ultimate future? Where can he go in order that he may use his intellectual gifts, since illness has deprived him of his physical powers?

I made some further inquiries both from education authorities and from voluntary bodies which specially cater for the education of handicapped children, and I found 9 severely handicapped children aged 15–16 years who are receiving special-school education. It is thought that 6 of them will be unable to receive sufficient care at home on leaving school, the cases of the other 3 being doubtful. In addition I found 5 16-year-olds in hospitals in this region, and a further 4, belonging to this region, in the children's hospital of a neighbouring region. These 18 young people suffer from a variety of diseases: muscular dystrophy (5 boys); cerebral palsy (2 boys, 2 girls); poliomyelitis (1 boy, 2 girls); fragilitas ossium (2 girls); spina bifida (2 boys); hydrocephalus (1 boy); Friedreich's ataxia (1 boy).

Of 8 difficult placement cases who left Chailey Heritage in the last three years, 3 went to other hospitals for further treatment, and 5 to accommodation provided by voluntary societies. This may sometimes be the best solution, but there is a great lack of such voluntary homes, and the waiting-lists are long

A spastic girl of 16, leaving a special school, was sent into a private hospital run by a sisterhood, and a boy with spina bifida has been in a chronic ward for four years, since he left school Yet another, with muscular dystrophy, now aged 18, has been in a chronic ward for two years, but fortunately with a few others aged 16–45 This hospital has accepted another muscular dystrophy patient aged 16

All in close touch with this problem are concerned at the lack of suitable provision for this class of youngster

POTENTIAL LONG STAY PATIENTS

During 1952–53 I made a survey, under the Leverhulme Research Awards, into the social problems of disabled persons living in Kent, in the 15–45 age-groups Of 340 persons visited in their own homes, I found 42, aged 25–45, who either by reason of failing relatives or of progressive disease, might be expected to require hospital admission within the next five years Of the 42, 19 were cases of disseminated sclerosis, and another 10 had other progressive diseases, 20 of the 42 were living with elderly parents, and 3 were living alone, the others were looked after by husband or wife

Older patients (aged 45–55) in chronic wards also deserve attention, especially those who are mentally alert 11 men and 23 women were specially referred to me because of their mental alertness, and there would undoubtedly have been more had I been looking for them If in planning for the future these patients are considered, with the younger ones, the numbers to be catered for will be much higher than those suggested by this survey

DISCUSSION

Young long stay patients are not only patients they are also human beings with diverse needs in the way of companionship, interest, occupation, and (perhaps the most fundamental need of all) the feeling of being "wanted" and of being some use in the world

I found that doctors, nurses, and almoners all agreed that it is not right to allow the young to remain indiscriminately with the old, but there was no uniform opinion as to how the problem should be tackled There is little, if any, spare money to use in the creation of anything new A few hospital management committees have made a start by gathering the younger patients together in one ward, often by exchange with older patients, but this in itself creates difficulties because such young patients are likely to occupy their beds for many years, hence they reduce the number of active beds in the hospital

In other hospitals the answer has been to place the patients in acute beds, but should the prevailing atmosphere, for the long-stay patient, be that of a busy acute ward? In chronic wards, however, he is usually surrounded by the old, the incontinent, and the dying The fact that one man, now aged 40, has become so used to his surroundings, after thirty bedfast years, that he does not want to be moved, does not prove that present accommodation is adequate but rather it shows that the power of adjustment in human beings is infinite

What type of accommodation is most suitable for the young long stay patient and what is available for him? What better use can we make of the resources at our disposal?

Is the answer to be found by grouping the young together within the curtilage of a general hospital with full ancillary services, where they have the chance of active treatment and rehabilitation? But what if this ends in transfer, within the same hospital, to a geriatric ward when the "young" grow "old"? Is it possible to bring in even more outside life than is at present done, so that the young patient may feel he belongs to the community outside, not only through their visits to him, but by his excursions into the normal world of social life, sport, and church worship? If that is the answer, should there be several small units in each region, to allow of reasonable access by relatives? Or should there only be one or two, in which resources can be pooled? How is a balance to be struck between the needs of the "difficult" and the very ill patient, and those of the other patients in a ward? Is a person to be judged as "young" by his date of birth or by his mental alertness, and at what age does he become "old"? What can be offered to the 16-year old? Are there any improvements which could be introduced, here and now, by those hospitals which already accommodate young long stay patients?

Finally, is this problem so widespread, that it should be considered for the country as a whole instead of being tackled by hospital management committees and regional hospital boards? Though widespread, it is perhaps not a large problem it need not call for the expenditure of large sums of money But it does call for the free use of knowledge and imagination so that these young long stay patients may have some chance to live the richer, fuller life which is surely their due

---

"MINOR" ADDICTIONS

Barbiturates, Methylpentynol, Tobacco

On May 23 the Ciba Foundation devoted a quarterly clinical forum to Major Consequences of Minor Addictions

Dr H **Pullar Strecker** (hon secretary, Society for the Study of Addiction) said that the World Healt Organisation's expert committee in 1950 and 195 recognised three groups of drugs

1 *Addiction producing*—Some drugs (notably morphine have a specific pharmacological action which will alway produce compulsive craving, dependence, and addiction u anybody With these drugs pharmacological action is paramount, psychological make up adjuvant Such drugs caus individual and sociological damage

2 *Habit-forming*—Other drugs never produce compulsiv craving, yet their pharmacological action is found desirable t some individuals to the point that they readily form a habi of administration—a habituation Administration can b interrupted without significant disturbances With them th psychological make-up is paramount, pharmacological actio adjuvant They cause no sociological damage

3 *Intermediate*—The pharmacological action of some drug is intermediate in kind and degree between groups 1 and 2 Compulsive craving, dependence, and addiction can develo in persons whose psychological make up leads them to see and find escape in drugs Psychological make up is th determining factor, but pharmacological action plays significant rôle

He himself prefers to classify them as (1) essentially malign, such as narcotics, (2) potentially malign, such as barbiturates and alcohol, and (3) essentially benign, such as tobacco But they can be compared according to various different criteria For instance, in terms of what people will pay to get their drug, narcotics come first, with tobacco a close second on the Continent after the late war there was hardly anything people would not and did not give in exchange for cigarettes But the hallmark of an addiction is the suffering entailed when it is unobtainable, which is worst with narcotics and really quite bearable with tobacco Another criterion is the difficulty entailed in discontinuing the drug by one's own unaided efforts—a difficulty by no means insuperable with tobacco In social effects—the extent to which it cuts across family life, work, duties, obligations, reputations, and so on—alcohol is easily worst, followed by narcotics and barbiturates Tobacco does not figure here at all, and that is why, not so long ago, we were rejoicing over the inroads that tobacco was making on the consumption of drink (Since 1900 the consumption of tobacco has increased two and a half times and the consumption of alcohol has decreased to about half) But unfortunately now that the connection between smoking and lung cancer has become well nigh inescapable, tobacco has displaced alcohol as the greatest danger to public health. By this criterion alcohol now takes second place, with barbiturates as the runner up Narcotics—perhaps because they are so well controlled in this country or perhaps because the British as a nation are not given to addiction—is no public health problem in this country

But how Dr Pullar-Strecker asked can the powers that-be afford to discourage smoking when it brings the State £030 million a year in revenue—more than enough to defray the nation s entire health services ? One suggestion might be to increase the taxation on pools and other forms of gambling measured against the physical corruption of lung cancer the supposed moral corruption of gambling appears almost a blessing but the money obtainable would he thought, be relatively negligible. In the fight against excessive drinking much has been done by taxation closing hours and counter attractions; but tobacco consumption would comfortably withstand a further increase in taxation and the other remedies are inapplicable. There remains education, by which it might be possible to induce young people not to take up smoking This should be done not so much by emphasising the potential danger as by making non-smoking worth their while. In this world you cannot make people think as you do but you can make it worth their while to do as you think. With those who are smokers already, education will cut little ice

BARBITURATE ADDICTION

Dr R. A. **Hunter** (York Clinic, Guy s Hospital) said that this century has seen a tremendous increase in awareness of psychiatric conditions, without an equivalent increase in psychiatric understanding The general practitioner is in the unhappy position of being taught to recognise conditions which he is powerless to treat What is he to do about the 50–75% of his patients whose symptoms seem to have their origin in the mind or emotional life ? The answer of course is drugs—sedatives, hypnotics, and stimulants In the U.S.A in 1048 enough barbiturate was manufactured to provide every inhabitant with about 30 grams a year In this country in 1919 almost 10% of all the drugs prescribed under the National Health Service were barbiturates, and today 15% would be nearer the mark It is therefore surprising that the dangers of this group of drugs are so little recognised.

A great deal of chronic invalidism is caused by the liberal prescription of barbiturates for minor physical and psychiatric symptoms, because suppression of symptoms is mistaken for treatment In milder cases with regular dosage and unfailing supplies withdrawal symptoms hardly appear; but if they do it is in the form of exacerbation of the original symptoms for which the drugs were prescribed and accordingly their significance as signs of a barbiturate habit is not appreciated by either doctor or patient. Though it has been thought that tolerance to barbiturates does not develop its existence is shown by the many patients who take barbiturates in hypnotic doses in the daytime without producing sleep—simply in order to keep going Psychical dependence will develop in about a month if the patient is given a barbiturate at night with two or three smaller doses during the day Physical dependence is best demonstrated by abrupt withdrawal of the drug sometimes undertaken on admission to hospital so that the patient's psychiatric condition can be followed without masking of the symptoms by drugs. In patients who have been on barbiturates such withdrawal may cause insomnia for as long as five days besides severe anxiety symptoms But once over this stage many are well enough to leave hospital in the words of Sir Samuel Wilks " the mere absence of treatment by physic is often a positive stage towards cure "

Many patients and their doctors are not aware that the original symptoms are maintained by the treatment While the barbiturates act, these symptoms are inhibited but each time the effect wears off they return At first it is only the contrast between being with and without the symptoms that makes the patient go on taking the drug but in time the symptoms of abstinence are added, so that when the drug wears off the patient is left with his original depression, insomnia, and anxiety, plus the same symptoms produced by the temporary withdrawal of barbiturates in the intervals between doses. The vicious circle of increasing and more frequent doses has started and finally the confusion of barbiturate intoxication is superadded Thus a mild psychiatric disturbance, amenable to one or two psychotherapeutic interviews is converted into a serious condition Patients who would not otherwise have done so may be driven to attempt suicide and are at this stage often diagnosed as suffering from endogenous depression and subjected to electro convulsions If the cause remains unrecognised leucotomy may be performed for what was originally an iatrogenic state of barbiturate intoxication, or a state of addiction which went unrecognised.

In conclusion Dr Hunter said that " to assess the danger of barbiturates is not to despise them I would simply plead for fewer drugs and more understanding of the patient s mind."

STIMULANTS AND DEPRESSANTS

Dr A D **Macdonald** (professor of pharmacology, Manchester) thought it would be odd if the synthetic chemist did not try to produce better stimulants and more controllable depressants than the caffeine and alcohol so long used by mankind

Among stimulants the amphetamines stand out head and shoulders: their value against fatigue and mild depression has been established and the likelihood of addiction is lessened by their being more efficient when used occasionally than when used regularly Amphetamine is also offered in combination with phenobarbitone and mephenesin, and these cocktails in tablets have fascinating pharmacological possibilities The presence of schedule IV poisons does not prevent a demand for them with which the manufacturers (he was told) cannot keep pace

Methylpentynol was introduced in America in 1951 as a short acting hypnotic but is now advertised here for the " emergencies " of daily life—public speaking interviews examinations, visits to the dentist. Trotter[1] reported that in the recommended dosage its effect on behaviour was negligible. Similarly in a test of accuracy in adding numbers Professor Macdonald found on the average, little change—performance being 5% better after amphetamine (10 mg) 6% worse after alcohol (2 oz 40% *v/v*) and 8% worse after methylpentynol (500 mg) But in two out of fifty students performance was 40% worse after methylpentynol, and in a test with dummy capsules he found it easy to tell which students had had the drug People who take the drug may exceed the recommended dose and it is not surprising that there have already been charges of car-driving under the influence. A young man who took seven capsules awaits trial for manslaughter Yet the drug is still unscheduled and advertised as safe and harmless

The potential value of drugs which will relieve anxiety states and even the milder forms of nervous tension is enormous said Professor Macdonald But in his opinion their use and advertisement without medical control and without restriction is to be deplored

---

[1] Trotter P *Lancet* 1951 ii 130.

TOBACCO

Miss **Flora Beck** (almoner, General Infirmary, Leeds) said that for the occasional smoker the aroma of tobacco and a faint dulling of emotional awareness provide a small distinctive addition to the pleasures of relaxation, but the physical and emotional effect is small. Under social pressure, however, it is easy to become acclimatised to smoking more heavily, and after a day's abstinence the first cigarette gives a feeling of physical and emotional relief of a kind and degree which is new. At this stage the body has readjusted to neutralise the effect of a constant overdose of nicotine; to go without smoking upsets what has become its normal state, and an artificial craving has been induced. Satisfaction of this craving gives a feeling similar to the normal satisfaction of some primary need; and where deprivation and frustration are present they can be superficially allayed in this way.

> "A need for affection, a need for food, a need for physical activity, a need for rest, a need for intellectual stimulus, a stirring of the spirit—all these, after a time, may be falsely decoded in the mind and presented to consciousness as one single simple cry: 'I want a cigarette.' The cigarette does give satisfaction. The duped conscious mind assumes that all is well. . . . In this way a tiny physical 'addiction' can become the focus for powerful inner drives—and it deflects them away from the constructive attempt to satisfy real needs."

Mass addiction to tobacco represents a vast drain on personal and national income, and does much to perpetuate the ills it claims to relieve. What can be done about it? The example of light smokers or non-smokers carries more conviction with the average smoker than rabid anti-smoking speeches. Though it is important to broadcast the dangers of smoking, this should be done rather to reinforce a positive policy than to frighten people off. Life is *pleasanter* when freed. A general trend in public opinion slightly against smoking would have a big effect, and in a general campaign the person to aim at is the "floating smoker."

The really habituated smoker, if he is to change, must *want* to control or give up smoking. He may then adopt one of three methods:

1. *Cut off completely and for good.*—Some do this and after a few weeks are no longer bothered at all. But where a psychological urge has been built up, this method may leave a permanent feeling that some tremendous pleasure has been renounced. This may bring fear of relapse, and the whole subject of smoking remains disturbing.

2. *Reduce by rationing.*—This needs a less drastic act of will at the start but constant lesser self-control. After readjustment, physical craving will be satisfied at a lower level.

3. *Start by stopping completely (if possible for at least three weeks), then smoke for a few days and give it up again.*[2]—During abstinence, when the physical craving has died down, the psychological urge is still building up. Smoking comes as an anticlimax: the expected strong satisfaction is not felt, and will not be, unless smoking is continued long enough to induce a physical craving again. It takes numerous repetitions of this to undo the conditioning which associates smoking with strong satisfaction; but the tendency to translate any inner tension into the feeling "I want to smoke" gradually dies out.

Whereas the mild physical "addiction" to smoking can be cured in a few weeks, it takes months or even years to rub out the mental habit pattern. "It is obviously much better," said Miss Beck, "never to become addicted. Those who take care not to exceed 10–15 cigarettes a week can safely enjoy smoking, if they wish, without fear of the habit taking charge."

In the discussion Dr. **Horace Joules** said that, though it is estimated that a million people in England and Wales will die from carcinoma of the bronchus before the end of the century, he is even more concerned at the 30,000 deaths annually from chronic bronchitis preceded by long years of discomfort and disability, which would be largely prevented if people would stop smoking. He accused the Ministry of Health of failing to tell the public about the harmful effect of tobacco, and he praised the *Journal of the American Medical Association* for refusing to accept tobacco advertisements. Prof. F. R. **Winton** spoke of the difficulty of preventing maladjustment and frustration in people who find life in modern communities unsatisfying, and referred to the decline of religious institutions. Addictions would vanish if psychiatrists could cure the disorders underlying them. Prof. W. D. M. **Paton** questioned whether we are tinkering with the surface of a deep human need, which would express itself in some other way if addiction were abolished. We should address ourselves to the nature of this fundamental need. Dr. A. **Levene** thought it would be instructive to make a study of the 10% of people *not* addicted to tobacco. Addiction to barbiturates or to methylpentynol is doctor-made, and therefore a different problem from smoking. Dr. **Keith Simpson** said that, given the opportunity, any nation is a nation of addicts. Tobacco and alcohol are minor addictions in adolescence, but may lead to major addictions such as marihuana, "goof pills," or heroin. Experience has shown that placing a drug on schedules I or IV cannot be relied on to prevent its abuse. Dr. **Pullar Strecker** referred to the addition of ipecacuanha to barbiturates, so that an overdose will cause vomiting, and predicted that pharmacologists will eventually devise means of making barbiturates addiction-proof.

BIRTHDAY HONOURS

The list of honours published on June 9 contains the names of the following members of the medical profession:

G.C.V.O.

Sir **Horace Evans**, K.C.V.O., M.D. Lond., F.R.C.P.
Physician to H.M. the Queen.

K.C.B.

Sir **John Charles**, M.D. Durh., F.R.C.P.
Chief medical officer, Ministry of Health, Ministry of Education, and Home Office.

K.B.E.

Sir **Alexander Macgregor**, O.B.E., M.D., LL.D. Glasg., F.R.F.P.S., J.P.
For services to public health in Scotland.

Knights Bachelor

Albert Ernest Coates, O.B.E., M.D., M.S. Melb., F.R.A.C.S.
Stewart lecturer in surgery, University of Melbourne.
Darcy Rivers Warren Cowan, M.B. Adelaide, F.R.A.C.P.
Consulting physician to the Royal Adelaide Hospital.
Harold Robert Dew, M.B. Melb., F.R.C.S., F.R.A.C.S.
Professor of surgery, University of Sydney.
Geoffrey Langdon Keynes, M.D. Lond., F.R.C.P., F.R.C.S., F.R.C.O.G.
Consulting surgeon, St. Bartholomew's Hospital.

C.B. (Military)

Surgeon Rear-Admiral **Seymour Grome Rainsford**, D.S.C., M.D. Dubl.
Major-General **Albert Sachs**, C.B.E., M.D. Dubl., M.R.C.P., Q.H.P., late R.A.M.C.

C.B. (Civil)

Walter Eric Chiesman, M.D. Camb., F.R.C.P.
Medical adviser, H.M. Treasury.

---

[2] In first describing this method (*Lancet*, 1953, ii, 392) Miss Beck recommended that after the period of abstinence, one should smoke so heavily as to induce aversion. This she now thinks unnecessary.

C.M G

Benjamin Keith Rank M.S Melb F.R C S F.R.A C S
Chief plastic surgeon Heidelberg Military Hospital Victoria

Allan Robert Stanley Vickers O.B E CH.M Sydney
For services to the Flying Doctor Service in Australia

C B E (Military)

Air Commodore Albert Frederick Cook, O.B.E L.R C.P.I

Brigadier Allen Lepard Crockford D.S O., O.B E M C M.B Camb., Q.H.S late R.A.M C T A

C B E (Civil)

Roger Gilbert Bannister, M.R.C.S
For services to amateur athletics.

Philippe Leslie Caro Carrier, M D Lond M.R.C.P
Senior medical officer Home Office

Charles William Atkinson Emery M.B Belf
Principal medical officer Ministry of Pensions and National Insurance

Mary Esslemont LL.D M.B Aberd J P
General practitioner in Aberdeen for services to medicine in Scotland.

Edward Thomas Bondfield Green M D
Senior bacteriologist, Institute for Medical Research Federation of Malaya.

Ewen Lewers Grove M D Melb F.R.A C P
Physician, Launceston Hospital Tasmania

Ivan Arthur Llewelyn Vaughan Jones M.B Glasg J.P
For services to the Ministry of Labour and National Service.

William Caldwell McClelland M.B Melb
For services to sport in Australia.

Frederick Grantley Morgan M.B Melb F R.A C.P
Director Commonwealth Serum Laboratories, Victoria

Frederick William Roques M CHIR. Camb F R.C.S F.R.C O G
Consultant in gynæcology to the R.A.F obstetrician and gynæcological surgeon Middlesex Hospital

Sir Leonard Rosenheim, M.D Camb F.R.C.P
Professor of medicine in the University of London at University College Hospital.

James Leslie Allan Will, M.B N.Z. F.R C.S E., F.R.A C.S
Orthopædic surgeon Christchurch General Hospital.

Donald Gordon Duff M C M B Edin., F.R C S E
Surgeon superintendent Belford Hospital Fort William

Lyell Maurice Barkley Hill, M B Belf
Regional medical officer British European Airways.

Alex Todd M C., D F C., M B Edin
For medical and missionary services in Northern Rhodesia.

Public Health

LYMPHOCYTIC MENINGO-ENCEPHALITIS IN THE MANCHESTER AREA

J O'H Tobin
B.M Oxfd Dip Bact

LECTURER IN BACTERIOLOGY UNIVERSITY OF MANCHESTER

Lymphocytic meningo-encephalitis (L.M E) is a syndrome which is due to many different micro organisms and which has been known by a variety of names since Wallgren in 1924 first drew attention to it as aseptic meningitis.' The six well known criteria laid down by him for its recognition have been modified as knowledge of the syndrome has increased and as agents producing similar but clinically distinguishable features have been demonstrated Wallgren (1951) noted over 20 viruses, spirochætes yeasts and protozoa as causes of L.M.E Viruses are involved most often in this syndrome, poliomyelitis being generally considered the most important However a large proportion of cases diagnosed as non paralytic poliomyelitis, even during an epidemic of this disease are due to other identified and unidentified agents (Tobin et al 1954)

Simple serological procedures are available for the diagnosis of infection with the widespread lymphocytic choriomeningitis, herpes simplex and mumps viruses for the leptospiræ and for certain of the arthropod borne varieties of encephalitis in those areas where they are known to occur More extensive tests are required for the diagnosis of poliomyelitis Coxsackie and other viruses.

Few reports give any real picture of the incidence of the L.M.E syndrome or of its ætiological agents, because figures are based on selected groups of the population often scattered over large areas Until L M.E is made notifiable any exact idea of its incidence will be unobtainable at present it is necessary to draw inferences from those cases admitted to hospitals or from samples tested in virus laboratories (Afzelius Alm 1951 Adair et al 1953 Virus Reference Laboratory 1953, Gard 1954 Nilsby 1954) In this paper the results are reported of investigations on the viral ætiology of L.M.E in one area served by a small virus laboratory

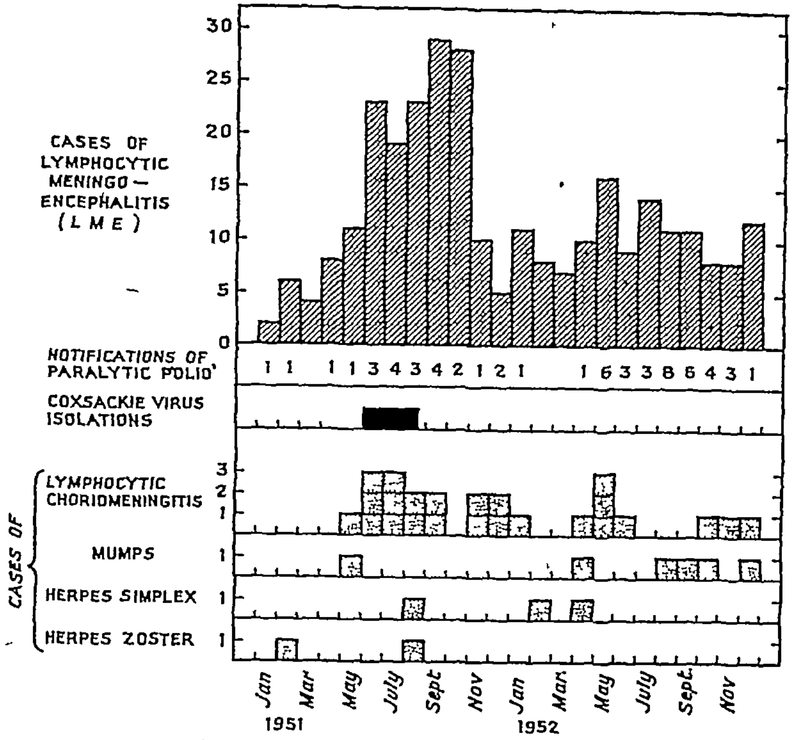
Laboratory Investigations

During 1951–52 samples for virus investigation were received from 201 patients in the Manchester area who were diagnosed as having non paralytic poliomyelitis, aseptic meningitis, lymphocytic or serous meningitis, meningo-encephalitis, encephalitis, and choriomeningitis. As meningitis and encephalitis in such cases rarely occur separately and as the pleocytosis in the C.S.F is predominantly lymphocytic these syndromes have been referred to in this paper as *lymphocytic meningo encephalitis*

Samples were received throughout both years with a peak during the summer and autumn of 1951 when the syndrome was encountered more frequently than normal by local physicians The number of patients from whom specimens were received is illustrated by the accompanying figure which also indicates when cases due to the test viruses occurred Each patient was investigated for the rôle of one or more of the following viruses in the ætiology of this syndrome

Lymphocytic Choriomeningitis

201 cases were examined by the complement fixation technique for specific antibody to this virus and occasionally by attempted isolation or by serum neutralisation tests in mice A diagnosis of this disease, which can often be made on *clinical and epidemiological grounds* with considerable assurance was accepted as being confirmed by either (1) a rising titre of complement



Monthly distribution of patients investigated

fixing or neutralising antibody, or (2) the presence of complement fixing antibody together with isolation of virus from the cerebrospinal fluid, blood, or throat washings 15 cases due to this virus were diagnosed in 1951 and 9 in 1952, 20 being in adults over fifteen years of age and 4 in children

Mumps

273 cases were examined by either the complement-fixation test using allantoic fluid as source of virus antigen, or in a few cases by the hæmagglutination inhibition test A fourfold rise in antibody titre was considered diagnostic of this infection in two samples of serum, one taken during the acute phase and another during convalescence Only 6 cases were due to this virus, but, as material was received only from patients who developed parotitis after the onset of the neurological signs or who had no parotitis, some cases may have been missed owing to lack of requests for serological confirmation 2 cases were in adults and 4 in children

Herpes Simplex

124 of the cases were investigated by the complement-fixation test using either antigen prepared from the chorio allantoic membrane of infected chick embryos or from infected allantoic or amniotic fluid. The majority of these tests were kindly done by Dr N L Modi This test was used as a screen and a rising titre confirmed by the neutralisation test using the chorio allantois of the developing chick embryo About 15% of the sera reacted non specifically with normal chorio allantoic extracts, and these were also tested for antibody by the neutralisation technique. 3 cases, 2 in children and 1 in an adult, were found to be due to infection with this virus

RESULTS OF VIRUS INVESTIGATIONS ON 291 CASES OF LYMPHOCYTIC MENINGO ENCEPHALITIS

Test virus	No of cases investigated			No of cases positive			% of cases positive		
	Total	15 yr or over	Under 15 yr	Total	15 yr or over	Under 15 yr	Total	15 yr or over	Under 15 yr
Lymphocytic chorio-meningitis	291	152	139	24	20	4	8 4	13 2	2 9
Mumps	273	143	130	6	2	4	2 2	1 4	3 1
Herpes simplex	124	61	63	3*	1	2	2 4	1 7	3 2
Encephalomyocarditis	41	22	19	0	0	0	0	0	0
Coxsackie†	62	8	54	4	0	4	6 5	0	7 5

* Including one case from which a " C " virus was also isolated
† Diagnosed by virus isolation or rise in specific antibody

Encephalomyocarditis Group

41 sera were tested by the neutralisation technique using 100 ID_{50} doses of MM virus, the serum virus mixtures being given by the intraperitoneal route in mice In no case were antibodies to this virus found

Coxsackie

During the summers and autumns of this period, one or more fæcal samples from 62 cases were investigated for " C " virus by the inoculation, either subcutaneously and/or intracerebrally, of suckling mice less than twenty four hours old Only 5 strains of virus were isolated from the 47 patients studied in 1951, and none from those in 1952 These were isolated from 4 patients, one being infected simultaneously with 2 " C " virus strains and another who had a concurrent primary herpes simplex encephalitis Another patient showed a significant rise in antibody to one of the " C " viruses during her illness 3 group-B type 3 strains were found and 2 group A, types 2 and 4, the latter being those associated with the dual infections

Herpes Zoster

Although no methods were known for the cultivation of herpes zoster virus in our laboratory at that time (Weller 1953), sera from 2 cases of herpes zoster with L M.E were investigated to exclude herpes simplex virus infection, because this virus has been isolated from zonal lesions (Beeuwkes 1939)

The above results are summarised in the table

Discussion

In this series the proportion of cases shown to be due to specific viruses was small Lymphocytic chorio-meningitis, herpes simplex, and mumps infection accounted for approximately 7% of the cases in children and 16 5% in adults, while none was found to be due to the encephalomyocarditis group of viruses. Lymphocytic choriomeningitis was associated with the two localised endemic areas in Manchester noted by Duncan et al (1951) Cases of this disease were generally clinically distinct from the other cases of L M E in having a prodromal phase before the onset of meningitis and a considerable proportion of them having a low level of sugar in the cerebrospinal fluid, a finding observed by Duncan et al (1951) and confirmed in the recent report of Adair et al (1953) from the United States The mumps cases, as would be expected, occurred when the disease was most prevalent Although 3 cases of herpes simplex infection occurred, this virus, and that of mumps, did not seem to cause as high a percentage of cases as in the series recorded by the American workers

The work of Curnen et al (1949) and Gabinus et al (1952) has indicated that the B group of the Coxsackie viruses can cause L.M.E and these viruses have been recovered from the cerebrospinal fluid of patients on two occasions (Gabinus et al. 1952, Hummeler et al 1954)

Gard (1954) thinks that they are responsible for a large proportion of the cases of this syndrome in Sweden However, no evidence could be found to suggest that they played any but a very small part as causal agents of L.M.E. in the Manchester area in 1951 when C viruses were known to be prevalent (Bury and Tobin 1952)

In 1951 the C virus isolations both from meningo encephalitis and Bornholm disease cases occurred before the L.M.E. reached its peak and both Gard (1954) and ...unen (1952) have noted that infections with these ...ruses may anticipate the poliomyelitis season ...eutralisation tests with the types of C' virus isolated ...d with three other types on the sera of patients ill in ...ugust to November confirmed that lack of isolation of ...ese viruses then was due to their absence in the patients ...sted

Lymphocytic choriomeningitis occurred more fre...ently in adults than in children—young housewives ...ing the most usual victims—while the Coxsackie ...uses were isolated from those in the younger age group ...erological studies using the HeLa cell-culture method ...cribed by Syverton et al. (1954) showed that polio...elitis infection was present in the area Of 11 indivi...uals tested 10 had antibody to type 1 9 to type 2 ...d , to type-3 poliomyelitis virus However only ... cases of paralytic disease were reported from South ...ast Lancashire in 1951 and 35 in 1952 The exact ...lationship of these viruses to L.M.E cannot be decided ...til we know the results of investigations now in progress ...Although L.M.E seemed to be more prevalent during ... summer and autumn a large proportion of the cases ...this series occurred during the winter and spring, ... until this syndrome is made notifiable much of its ...idemiology will be shrouded in obscurity

Thanks are due to the many physicians who sent in sera ...m patients under their care to Dr Sven Gard for the ... virus and to Mrs. B M Snape for her valuable technical ...sistance

DENTAL CARE FOR MOTHERS AND CHILDREN

The Ministry of Health has issued a memorandum ... dental services provided by local health authorities. ... memorandum has been prepared in agreement ...h the Ministry of Education The following is a ...mary of its recommendations

EXTENT OF THE SERVICE

A satisfactory service is defined as providing for the ...amination of every expectant mother and the periodical ...amination of pre-school children followed by the ...vision of any necessary treatment Progress towards ... comprehensive service of this sort has been made ...icult by the shortage of dentists in the public dental ...rvice, but the numbers are now increasing and the ...istry suggests that authorities should review this ...rt of their maternity and child welfare service to ...re that they are making the best use of the available man power and are making such expansion as can be financially afforded

The object of treatment should be the conservation and retention of the natural teeth whenever possible and all forms of treatment should be available apart from those for which reference to hospital is necessary In a satisfactory service the number of teeth filled for expectant and nursing mothers and pre-school children should greatly exceed the number of teeth extracted. Only a few authorities have so far been able to achieve this standard

PROVIDING THE SERVICE

A local authority is not fulfilling its duty by referring mothers and children to the general dental services for any necessary advice and treatment The general dental services are of course available to the ' priority classes but some dentists are unwilling to treat small children and there is in any case no system for ensuring that these classes are put in a preferential position in relation to other patients Mothers and young children do not form a sufficiently large class to justify an entirely separate dental service and the service should therefore be coordinated with the school dental service for joint use of staff and premises Dental officers employed by the local health and education authorities should devote not less than one eleventh of their time (i e., one session of 3 hours in a 33 hour chairside week) to maternity and child welfare work This division of time should be applied even though for the present the full demands of the school and the maternity and child welfare dental services cannot be met

It is important that the dental part of the local health services should be directed by a chief dental officer who should be the principal school dental officer This officer should direct the work of the dental officers, train those who are inexperienced in the routine work of clinics, and be available for consultation It would be part of his duty to advise the medical officer of health on dental factors in health education and to train other members of the health department staff—e.g health visitors actually engaged in this work

Within the limits of expenditure available some priority should be given to the provision of further clinics (some notes on planning are given in an appendix to the memorandum) Where existing clinics are not fully used greater use can sometimes be made of them by the part time employment of general dental practitioners on a sessional basis a method which has enabled many authorities to provide in present circumstances a much more comprehensive service Evening sessions might supplement or replace morning or afternoon sessions. This system has been used with success by a few authorities, and mothers welcome the opportunity of attending for treatment at a time when the father is usually able to look after the children

So that they can spend the maximum time on operative surgery dental officers should be relieved as much as possible of other duties For this reason general anaesthetics should be administered by medical practitioners if necessary engaged for this purpose on a sessional basis. Oral hygienists can also relieve dental officers of considerable routine work in scaling and polishing teeth

Modern equipment should be provided so that as many patients as possible can be treated and so that the inevitable strain of dental work, particularly with children is minimised. X ray units should be available to serve all clinics in full time use Arrangements can be made for outside technicians to construct dentures, crowns, or inlays. If over 400 dentures or orthodontic appliances are required annually it may be advisable to consider setting up a dental laboratory and employing a dental technician.

COÖPERATION WITH OTHER SERVICES

Close coöperation with other branches of the maternity and child welfare service is essential. It is important that women should obtain dental treatment in the early stages of pregnancy and those attending antenatal clinics should be referred as a routine by the doctor or midwife to the dental officer, unless, of course, they prefer to make their own arrangements It is often an advantage to hold antenatal and dental sessions at the same time It is important to detect and treat slight defects early, and even if it is impossible to provide routine examination to all mothers, it should at least be provided for those undergoing their first pregnancy Mothers attending child-welfare clinics should be encouraged to bring their children for regular dental examination and treatment from the age of $2^1/_2$

DENTAL HEALTH EDUCATION

Education about dental health should be an essential part of the general health teaching programme As part of this programme, dental officers should, when staffing considerations permit, visit antenatal centres where there is no dental clinic, to give group talks and be available for consultation by the patients If oral hygienists are employed, an important part of their work is in dental education, and particularly in introducing young children to their first experience of dentistry Health visitors should, of course, continue to include dental health education in their advice to mothers they are in a particularly favourable position to advise mothers on the right types of food for children They should be able to recognise the early development of habits leading to deformities of the teeth and jaws such as thumb, finger, or tongue sucking Simple explanations of the cause of dental decay and the value of the filling of teeth as opposed to their premature loss should also be undertaken by them Another appendix to the memorandum gives some notes on the means of promoting preventive dentistry to guide those undertaking these duties

There are more opportunities for group teaching on dental care now that many health visitors give talks to groups of parents and others At antenatal clinics mothers are usually ready to accept advice on the need for dental treatment Home visits by the health visitor or midwife should ensure that the advice is carried out by treatment when necessary and in all cases by reference to hygiene and food value

The Ministry of Health has produced a simple single paged illustrated leaflet, suitable for the use of health visitors, which will be supplied free to authorities on request The Ministry has also reprinted the 12 panel display set, *Take Care of Your Teeth*, first sent to all local health authorities in November, 1951 Copies of this set are also obtainable free Details of these and other publicity material are given in a third appendix to the memorandum

Poliomyelitis Vaccine

The United States Public Health Service last week issued a report on the Salk poliomyelitis vaccine.[1] The breakdown of the mass vaccination programme is largely attributed to the incompatibility of the original formula with mass-production methods The experience of manufacturers showed " that the process of inactivation does not always follow the original concept " set out by Dr Salk. The Federal government lacked " adequate " procedures for determining manufacturers' performance and control because there were insufficient statistical data or experience on which they might be based The government's biological control arrangements have accordingly been reorganised, and a new Division of Biologics Standards has been created, with increased powers and facilities, to replace the Laboratory of Biologics Control, that had been in charge of the clearance of the vaccine.

During manufacture, the report states, the formalin used for inactivation often failed to reach minute particles of live virus The original safety tests were designed " primarily to demonstrate mass contamination resulting from accidents in manufacture and not small amounts of residual live virus which the process was believed to reduce to an immeasurably low and harmless level " Data obtained in a study of manufacturers' processes indicated that a single negative test (which was what the old safety standards required) was unreliable, and the minimum requirements were raised

The report gives some reasons for believing that Cutte vaccine may have contained live virus

> " The interval between injection of vaccine and first paralysis in Cutter associated cases ranged from five to twenty days The median case occurred in the ninth day and th spread was from six to fourteen days This finding parallel the frequency distribution of incubation periods in monkey infected by intramuscular injection of virus Moreover th distribution of cases following the injection of Cutter vaccin is the expected distribution in a common source outbreak o polio resulting from a single exposure to the infectious agent

Another similarity to experience with monkeys was th " high degree of correlation " between the site of injectio and the site of first paralysis

In a letter accompanying the report, Dr Leonard A Scheele, the Surgeon-General, says that " events which i the traditional course of scientific development wou have covered years were telescoped into months and, a result, both successes and failures have been magnifie In the long run, however, the nation and the worl will surely have gained from efforts to speed the avai ability of an effective immunising agent against th disease "

Parliament

The Queen's Speech

THE first session of the new Parliament was opene by the Queen on June 9 The Government have decide that the session shall continue for fifteen months, extending to the autumn of next year It is hoped to plac on the Statute Book some measures introduced but no passed in the last session, including the Road Traffi Act

The gracious Speech announced that Bills would als be introduced to safeguard the health and provide fo the safety and welfare of those employed in agricultur and forestry, to extend the period during which famil allowances were payable for children who remained a school, and to reduce the pollution of the air by smok and other causes In the light of proposals recentl agreed among the local authority associations the Government were examining the problems of local government in England and Wales with a view to introducing legislation on the subject While maintaining a high rate of house building, the Government would encourage action to secure the more rapid clearance of slums in both town and country and to relieve urban congestion Such legislation as might be found necessary uld be introduced to further these objects. Further nsideration would be given to the composition of the use of Lords.

QUESTION TIME

Prohibition of Heroin

Replying to questions asking on what evidence the Ministry f Health held that an efficient substitute for heroin existed the treatment of disease and what consultations had taken ce with *medical practitioners before the decision to limit* manufacture to small quantities for scientific purposes r Iain Macleod Minister of Health, said that the British armacopœia Commission were of the view in 1950 that table alternatives existed and deleted the monograph on e drug from the 1953 edition of the *British Pharmacopœia* e Standing Medical Advisory Committee were consulted d endorsed this view As a result Mr Macleod had d the Home Secretary that there was no obstacle from standpoint to responding to the appeals of the World alth Assembly and Economic and Social Council to prohibit e manufacture of the drug Replying to Mr Somerville Hastings he added It is true that there are people who ve that for a limited range of afflictions there is no true stitute for heroin. The point is that we have to weigh is against the larger claim of playing our part in combating thing which is a very substantial social evil all over the rld, and although there may be very little evidence of diction in this country it is entirely desirable that if we n get international agreement we should prohibit the nufacture of the drug everywhere

r. Walter Elliot: Is it not a fact that the drug is really reat use in certain cases and cannot be dispensed with? ll the Minister bend his utmost efforts to ensuring that lies are made available to reputable practitioners, as has ously been done with many drugs as dangerous as this

r. Macleod: *I will gladly take that into account* I can do is to take the very best advice that is available me, which is that of my Standing Medical Advisory Com tee which includes the presidents of all the royal colleges, chairman of the council of the B.M.A the president of the ral Medical Council and many other people. Their view rely one to which we must give the greatest attention

Replying to a further question asking whether in view of the sts of the B.M.A and of the medical profession through the country against the threatened withdrawal of heroin Home Secretary would now permit the manufacture of drug in limited quantities for use by medical practitioners, subject to a ban on its export, Sir Hugh Lucas Tooth under-secretary of State for the Home Department d that the council of the B.M.A. had asked the Home tary to receive a deputation on this subject and he had ed to do so

Poliomyelitis Vaccine

Replying to a question, Mr Macleod said that a member he staff of the Medical Research Council had just returned a visit to the United States where he had been studying latest developments in regard to poliomyelitis vaccine report was at present being considered.

Dr Barnett Stross Is it not a fact that some of the results of the use of the Salk vaccine in the United were due to the fact that the virus in the vaccine was completely killed? If it is used here may we take it t the greatest care will be taken to see that no such ent occurs?—Mr Macleod: It seems probable that xplanation of the Cutter vaccine incident was that it ained live virus We in this country will be content only the very highest standards before we go ahead.

Royal Free Hospital Group Inquiry

Replying to a question Mr Macleod said that he had seen report of the subcommittee of the board of governors of Royal Free Hospital group set up to inquire into the edure for dealing with casualties at the Hampstead eral Hospital He was informed that the report had been pted by the board. They were satisfied that the pro re laid down was in itself satisfactory if properly followed he saw no reason to differ from that view What was ded was to see that it was properly followed which he sure that all concerned would now endeavour more than r do.

Medicine and the Law

A Difficult Transfusion

A RECENT inquest[1] investigated a death which followed an incompatible transfusion The patient a woman aged 54 was admitted to hospital with high intestinal obstruction valvular disease of the heart, and auricular fibrillation her blood urea was raised. Operation relieved the obstruction, and a transfusion of two bottles was ordered. Two bottles of group A blood were given to the patient, who was of group O the next day she was found to be jaundiced and her urinary output decreased but after a few days the jaundice faded and the urinary output increased again Nevertheless the blood urea remained high and the patient died 16 days after operation At necropsy the kidneys showed chronic pyelonephritis, thought to be sufficient to account for the raised blood urea, and the coroner accepted this view agreeing that the blood transfusion was not responsible for the patient's death

The interest of this case lies in the difficulties encountered by the technicians in grouping the patient's blood According to the local press report,[1] which is an unusually good one, a sample of anti A grouping serum agglutinated a number of samples of group O cells The most likely explanation of this is that the particular tube of grouping serum used was contaminated by bacteria and had become pan agglutinating—bacteriogenic hæmagglutination

Friedenreich[2] has shown that a few strains of bacteria can modify cells so that they are agglutinated by all human sera even those of group AB (the Hubener Thomsen phenomenon or T-agglutination) while Grove and Crum[3] and Davidsohn and Toharsky[4] have described the reverse phenomenon whereby a sample of serum becomes capable of agglutinating all human cells (H agglutination which has nothing to do with the rare antibody anti H)

It seems possible that in this case H agglutination may have been responsible for the technicians difficulty the regional transfusion centre found nothing wrong with the serum, but it seems possible that they received not the actual tube of serum which had been used, but another tube containing a sample of the same batch of serum which had not been contaminated by the rare bacterium which causes H agglutination Anyone unaware of this variety of bacteriogenic hæmagglutination might assume that an unused tube of the same batch would be preferable to the almost empty tube which had caused the trouble

The technicians also had difficulty in cross matching blood of group A with the recipient's serum but they ascribed this difficulty to the presence in the recipient's serum of macromolecular plasma substitutes, of which large volumes had been administered. One explanation is that they may have failed to distinguish between true agglutination (which was present) and rouleaux formation or *pseudo-agglutination* (which may also have been present) which often occurs when any blood cells are mixed with macromolecular colloids such as dextran This difficulty is well known but Marston[5] has shown that it can be overcome by using the Sheffield technique[6] in which cells and serum are incubated for about 1½ hours, after which the supernatant is removed and replaced by an equal volume of 20% bovine albumin the test being read microscopically 15 or 20 minutes

later, and Bowley and Dunsford[7] recommend that in such cases the anti-globulin technique should be used

Finally, having noted the difficulty in cross-matching, the two technicians decided that they must rely on the biological test in this about 50 ml blood is administered within 30 minutes, and if no reaction occurs during that time it is concluded that the blood is compatible This procedure can be refined by comparing the bilirubin levels of pre-transfusion and post transfusion samples of blood The technicians might not have realised that many incompatible transfusions do not cause any immediate reaction, and it seems that they were unaware of the Sheffield technique and its use for recipients who have received macromolecular plasma substitutes It is also probable that they were not familiar with the possibility of bacteriogenic agglutination This is not surprising, for most technicians, and many pathologists who work outside transfusion centres, would be equally unfamiliar with these possibilities Nevertheless, the situation of these technicians is one in which other technicians or junior pathologists may unhappily find themselves, and they should always have a chance of ready help from an expert Under the circumstances the technicians in this case acted wisely, within the limits of their knowledge and experience

Coitus Interruptus

The recent case of Knott *v* Knott[8] raises again the troublesome question of how far the practice of coitus interruptus should be treated as a ground for dissolving a marriage It is necessary in this connection to distinguish clearly between nullity and divorce A decree of nullity may be obtained on the inability or wilful refusal of one of the spouses to consummate the marriage It is still not clear whether insistence by the husband on coitus interruptus amounts to non consummation In the leading case of Baxter *v* Baxter,[9] in which the House of Lords decided that insistence by the wife on the use of contraceptives did not amount to non consummation, the question of coitus interruptus was specifically left undecided Later that year (1948) Mr Justice Finnimore, in the case of Grimes (otherwise Edwards) *v* Grimes,[10] granted a decree of nullity on the ground that the practice of coitus interruptus contrary to the wife's wishes amounted to non-consummation In a case decided only three days later—White (otherwise Berry) *v* White[10]—however, Mr Justice Willmer held exactly the opposite, coitus interruptus was not wilful refusal to consummate, although it might be legal cruelty if it resulted in injury to the wife's health

Mr Justice Willmer's decision was followed by Mr Justice Hodson in the case of Cackett (otherwise Trice) *v* Cackett (1950) His Lordship added that the court would be driven into an impossible position if it tried further to define what amounted to normal sexual intercourse between normally formed people, for, where a woman alleged that the man had failed to complete the sexual act, the court would have to inquire exactly at what stage emission took place or what degree of satisfaction was reached by the woman

There the position with regard to nullity remains Nevertheless, as suggested by both Mr Justice Willmer and Mr Justice Hodson in the cases just mentioned, a decree of divorce (as distinct from nullity) may be obtained on the ground of cruelty Legal cruelty has been defined as conduct of such a character as to have caused danger to life or limb or to bodily or mental health, or as to give rise to a reasonable apprehension of such danger A decree on the ground of coitus interruptus was in fact obtained in Walsham *v* Walsham (1949), in that case the husband persisted in withholding full intercourse although warned by his wife and by doctors of the probable consequences for her health which did in fact ensue

The new case of Knott *v* Knott carries the matter a stage further, since in this case a divorce was granted although the husband had not been warned by doctors of the consequences likely to result to his wife

The husband and wife were married in 1942 when she was not quite 17 and he was 22 She was of a sensitive disposition more liable than most people to be affected by events, and sh greatly wanted to have a child. The man was insensitive to th point of recklessness and did not want children After marriag they had no home of their own but lived with her parents there were long separations due to the war, from which h returned in 1945 During the ensuing years the husband ofte acted in an aggressive manner towards the wife and ther were quarrels between them In 1946 the wife was ill wit tuberculosis In 1953 the husband left the wife, who refuse to follow him and continued to live in her parents hom Throughout substantially the whole period of the marriage had refused full sexual intercourse and had practised coit interruptus against her will He had not received advi from any doctor that the continuance of this practice wou injure her health

Mr Justice Sachs held that the husband's conduc viewed as a whole, amounted to cruelty, further, t refusal to allow the wife a child and the practice of coit interruptus in disregard of whether it injured her health not, coupled with the obvious injury to her healt amounted to cruelty even though he had not been warn by doctors of the potential results His Lordsh said

> "I am not prepared to hold that his wife's deterioration health was due to an active intent to injure his wife. I hold that in determining to continue with coitus interrupt and in refusing to let his wife have children he was reckl of the effect on his wife and that his conduct was inexcusa
>
> I would hold that for a man deliberately and with good reason permanently to deny a wife who has a norma developed maternal instinct a fair opportunity to have e a single child is of itself cruelty when injury to herself res and when the husband adopts a course which preserves himself a measure of sexual enjoyment"

Refusal to have a Child

In another recently decided case—Forbes *v* Forbe —it was the husband who obtained the decree, it bei held that the wife's conduct in refusing to have a ch amounted to cruelty

The parties were married in 1945, both were then about Before the marriage the wife had never raised any object to having children, and she knew that the husband particularly fond of children After the marriage the w insisted on the use of contraceptives, at first the husb reluctantly agreed to use them himself, but later the w herself used them He attempted to persuade her to hav family, but she made various excuses and avoided discuss the subject as far as possible On occasions she taunted h about his desire for children By 1950, as a result of refusal to have free intercourse, their relationship had beco strained In February, 1953, the wife for the first ti definitely refused to have children and in November, 19 the parties separated By that time the husband was in bad state of health as a result of her refusal to have childre

Mr Commissioner Latey held that the wife's conduct caused injury to the husband's mental health, her cond was intentional in that she pursued it although she knew th her persistence was causing him anxiety and misery, acco ingly she had been guilty of cruelty and the husband w entitled to a decree In the course of his judgment the learn commissioner said "Quite apart from the exhortation in t solemnisation of matrimony that, first, Christian marria was ordained for the procreation of children, I cannot igno the fact that it is a natural instinct in most married men propagate the species and to bear the responsibilities an enjoy the comforts of their own children If a wife deliberate

[11] All England Law Reports, 1955 vol 2, p 311

> and consistently refuses to satisfy this natural and legitimate craving, and the deprivation reduces the husband to despair and affects his mental health, I entertain no doubt that she is guilty of cruelty

It would appear that these words are subject to the qualification that the wife's refusal must be without justification. For as Lord Justice Denning has said

> Where a man takes contraceptive measures against the will of his wife without reasonable excuse for so doing, it is easy to infer that he does it with intent to inflict misery on her but when a wife takes contraceptive measures or asks her husband to do so, her conduct can often be attributed to fear of consequences to herself without any intention of injury to him In the present case however, the wife was on record as saying that she had no fear of childbirth, and the learned commissioner had no difficulty in finding that the wife's intentional acts amounted to cruelty

Baby Sent Out Too Soon?

An infant who was discharged from hospital two days after birth died five days later from pneumonia. The inquest jury considered that the infant had been sent out too soon.[11]

> The baby was born on May 15 On May 17 the hospital told the father that his wife and the baby were to be sent home that evening They arrived home in an ambulance at 9 P.M that night when it had been snowing and it was cold, wet and [illegible] The father said in evidence that he had taken every precaution in preparing and warming the room into which his wife and baby were taken. On May 20 the baby was ill and a doctor ordered his removal to hospital where he died on May 22.
>
> The mother said in evidence that she did not think that the child had on enough clothing when it was discharged the baby seemed cold when they arrived home A staff nurse said that she wrapped the baby in blankets, and thought it was sufficiently guarded against the weather Asked if she approved of a baby going out of hospital so soon after birth, the midwife said that this was due to the bed situation; they could not do anything else It would be ideal she said, if there were bigger hospitals with better accommodation so that babies might be able to stay there for up to fourteen days.
>
> Medical evidence was given that every precaution was taken with the child and that there was nothing unusual in discharging a healthy mother and child after two days
>
> Summing up the coroner said it might strike the jury that once a decision to discharge the baby had been taken it was acted upon and had to go through. You may feel there is some lack of cohesion, coördination or supervision on the part of the hospital staff.
>
> Returning a verdict of death from natural causes, the jury added a rider that the baby was sent out of hospital too soon and that the standing order operative in the obstetric ward of the hospital regarding the discharge of mothers and such young babies be made more elastic

Newspaper's Account of an Operation

In January a newspaper published[12] an account of an operation performed by a thoracic surgeon at the Churchill Hospital Oxford The surgeon objected to this article which he had not in any way authorised He objected not only on the grounds of unwanted publicity for his name and the inaccuracies in the article but because he felt that the article might rouse unfair fears in the minds of patients who might believe that they suffered from a similar condition The Medical Defence Union accordingly instituted proceedings on his behalf against the newspaper and its issue of April 24 contained a correction of the inaccuracies and an apology to the surgeon

INTERLUDE

The water murmurs beside me murmurs ceaselessly
While I sit still, content
My moment taken out of the current of time
The dry stones of the rocky watercourse
Pale as bleached bones, are silent as time past
While the water murmurs. Through these pared stone
Bones of the land laid bare the river flows
Deep through the narrows and spreads wide
Into a sheet of silken blue spread at my feet;
Its satin smooth blueness frayed into purple
Into the rough, purple splatches of shallows,
As I still sit stilled in the moment between
Past and present This is the moment of no momentum
Poised between memory of pleasure past
And foresight of delight
So I sit relaxed caressed by the sun and teased
By an easterly breeze looking towards a steep hillside
Where tender green of the new grass and dusty pink of
full budded trees
Please my spring sap running senses. I see with approval
The sinuous strength of the tree that thrusts
Its dark twigs above me thrusts them into the sky
With their gleaming golden spear-sharp buds
Held high, thrustingly overflowing with life And the water
murmurs
Under the cover of ceaseless plasholing rushing
Comes softly a lazy liquid gurgle
An undertone an aside of the lively river
Over the colour flickering lights of small wet boulders
Shine and signal their silent delights
While the water murmurs And I sit still

* * *

This year we sought sunshine and warmth in Spain and as by products, our search brought us one mild adventure and one diagnostic triumph

The first began on a journey by bus to San Feliu we were a willing audience to floods of abuse at the iniquitous charges of the bus from an elderly French couple and when in the evening we were taking tea on the pavement in the square they came up They were not going back in the *maudit* bus; they had hired a boat, would we share it? It had a motor oh yes! It would take only two and a half hours. Madame was the leader firm and masterful We agreed but when we saw the boat we realised that our friends were not only enterprising but intrepid. The words of the Breton sailor's prayer came into my mind: O God my boat is so small and Thy sea is so large However ashamed to jib we climbed in. The sky was greying the wind rising the boat, overloaded with six adults (two crew) faltered at the start but after rounding the point chugged cheerfully along We hugged the forbidding coast Great cliffs towered above us. Pine trees grew in clefts of the rock, almost to the water's edge We passed an occasional sandy beach at the foot of an olive grove, caves, islets, and one house perched on a height, and finally hauled up in our own bay before the hated bus could have arrived

This led to our diagnostic triumph The French couple invited us to tea A Belgian lady came in distraught her son, aged six was very ill; he had developed a cough in the plane The Spanish doctor had seen him in the morning and had given an injection of penicillin but she could not understand what he had said about the diagnosis Would the English physician tell her what was the matter with Alexander? I said doubtfully that I would try realising that the Spanish doctor had probably temporised for lack of evidence As I left the tea table *my surgical colleague* who can turn Centigrade to Fahrenheit in a trice murmured They say his temperature is 103 Luck was with me—the child would not cough there were no Koplik's spots, but as I was percussing his chest I saw a faint incipient rash and plumped for measles.

I described the course of the illness, outlined the regime, and left amid general satisfaction and relief with later and Bowley and Dunsford[7] recommend that in such cases the anti globulin technique should be used

---

[11] Manchester Guardian June 7 1955. Birmingham Post June [illegible] 1955

[12] The People, Jan. 9 1955.

Finally, having noted the difficulty in cross matching, the two technicians decided that they must rely on the biological test in this about 50 ml blood is administered within 30 minutes, and if no reaction occurs during that time it is concluded that the blood is compatible This procedure can be refined by comparing the bilirubin levels of pre transfusion and post transfusion samples of blood The technicians might not have realised that many incompatible transfusions do not cause any immediate reaction, and it seems that they were unaware of the Sheffield technique and its use for recipients who have received macromolecular plasma substitutes It is also probable that they were not familiar with the possibility of bacteriogenic agglutination This is not surprising, for most technicians, and many pathologists who work outside transfusion centres, would be equally unfamiliar with these possibilities Nevertheless the situation of these technicians is one in which other technicians or junior pathologists may unhappily find themselves, and they should always have a chance of ready help from an expert Under the circumstances the technicians in this case acted wisely, within the limits of their knowledge and experience

Coitus Interruptus

The recent case of Knott *v* Knott[8] raises again the troublesome question of how far the practice of coitus interruptus should be treated as a ground for dissolving a marriage It is necessary in this connection to distinguish clearly between nullity and divorce A decree of nullity may be obtained on the inability or wilful refusal of one of the spouses to consummate the marriage It is still not clear whether insistence by the husband on coitus interruptus amounts to non consummation In the leading case of Baxter *v* Baxter,[9] in which the House of Lords decided that insistence by the wife on the use of contraceptives did not amount to non consummation the question of coitus interruptus was specifically left undecided Later that year (1948) Mr Justice Finnimore, in the case of Grimes (otherwise Edwards) *v* Grimes,[10] granted a decree of nullity on the ground that the practice of coitus interruptus contrary to the wife's wishes amounted to non consummation In a case decided only three days later—White (otherwise Berry) *v* White[10]—however, Mr Justice Willmer held exactly the opposite, coitus interruptus was not wilful refusal to consummate, although it might be legal cruelty if it resulted in injury to the wife's health

Mr Justice Willmer's decision was followed by Mr Justice Hodson in the case of Cackett (otherwise Trice) *v* Cackett (1950) His Lordship added that the court would be driven into an impossible position if it tried further to define what amounted to normal sexual intercourse between normally formed people, for where a woman alleged that the man had failed to complete the sexual act, the court would have to inquire exactly at what stage emission took place or what degree of satisfaction was reached by the woman

There the position with regard to *nullity* remains Nevertheless as suggested by both Mr Justice Willmer and Mr Justice Hodson in the cases just mentioned, a decree of divorce (as distinct from nullity) may be obtained on the ground of cruelty Legal cruelty has been defined as conduct of such a character as to have caused danger to life or limb or to bodily or mental health or as to give rise to a reasonable apprehension of such danger A decree on the ground of coitus interruptus was in fact obtained in Walsham *v* Walsham (1949) in that case the husband persisted in withholding full intercourse although warned by his wife and by doctors of the probable consequences for her health which did in fact ensue

The new case of Knott *v* Knott carries the matter a stage further, since in this case a divorce was granted although the husband had not been warned by doctors of the consequences likely to result to his wife

The husband and wife were married in 1942 when she was not quite 17 and he was 22 She was of a sensitive disposition, more liable than most people to be affected by events, and she greatly wanted to have a child The man was insensitive to the point of recklessness and did not want children After marriage they had no home of their own but lived with her parents, there were long separations due to the war, from which he returned in 1945 During the ensuing years the husband often acted in an aggressive manner towards the wife and there were quarrels between them In 1946 the wife was ill with tuberculosis In 1953 the husband left the wife, who refused to follow him and continued to live in her parents home Throughout substantially the whole period of the marriage he had refused full sexual intercourse and had practised coitus interruptus against her will He had not received advice from any doctor that the continuance of this practice would injure her health

Mr Justice Sachs held that the husband's conduct viewed as a whole, amounted to cruelty, further, the refusal to allow the wife a child and the practice of coitus interruptus in disregard of whether it injured her health or not, coupled with the obvious injury to her health amounted to cruelty even though he had not been warned by doctors of the potential results His Lordship said

> "I am not prepared to hold that his wife's deterioration in health was due to an active intent to injure his wife I do hold that in determining to continue with coitus interruptus and in refusing to let his wife have children he was reckless of the effect on his wife and that his conduct was inexcusable
>
> I would hold that for a man deliberately and without good reason permanently to deny a wife who has a normally developed maternal instinct a fair opportunity to have even a single child is of itself cruelty when injury to herself results and when the husband adopts a course which preserves to himself a measure of sexual enjoyment"

Refusal to have a Child

In another recently decided case—Forbes *v* Forbes[11]—it was the husband who obtained the decree, it being held that the wife's conduct in refusing to have a child amounted to cruelty

The parties were married in 1945, both were then about 20 Before the marriage the wife had never raised any objection to having children, and she knew that the husband was particularly fond of children After the marriage the wife insisted on the use of contraceptives, at first the husband reluctantly agreed to use them himself, but later the wife herself used them He attempted to persuade her to have a family, but she made various excuses and avoided discussion of the subject as far as possible On occasions she taunted him about his desire for children By 1950, as a result of her refusal to have free intercourse, their relationship had become strained In February, 1953 the wife for the first time definitely refused to have children and in November, 1953 the parties separated By that time the husband was in a bad state of health as a result of her refusal to have children

Mr Commissioner Latey held that the wife's conduct had caused injury to the husband's mental health, her conduct was intentional in that she pursued it although she knew that her persistence was causing him anxiety and misery, accordingly she had been guilty of cruelty and the husband was entitled to a decree In the course of his judgment the learned commissioner said "Quite apart from the exhortation in the solemnisation of matrimony that, first, Christian marriage was ordained for the procreation of children, I cannot ignore the fact that it is a natural instinct in most married men to propagate the species and to bear the responsibilities and enjoy the comforts of their own children If a wife deliberately

and consistently refuses to satisfy this natural and legitimate [illegible] and the deprivation reduces the husband to despair and affects his mental health, I entertain no doubt that she is guilty of cruelty

It would appear that these words are subject to the qualification that the wife's refusal must be without justification. For as Lord Justice Denning has said "Where a man takes contraceptive measures against the will of his wife without reasonable excuse for so doing it is easy to infer that he does it with intent to inflict misery on her, but when a wife takes contraceptive measures or asks her husband *to do so* her conduct can often be attributed to fear of consequences to herself without any intention of injury to him." In the present case however the wife was on record as saying that she had no fear of childbirth, and the learned commissioner had no difficulty in finding that the wife's intentional acts amounted to cruelty

Baby Sent Out Too Soon?

An infant who was discharged from hospital two days after birth died five days later from pneumonia The inquest jury considered that the infant had been sent out too soon.[12]

The baby was born on May 15 On May 17 the hospital told the father that his wife and the baby were to be sent home that evening. They arrived home in an ambulance at 9 P.M at night when it had been snowing and it was cold wet, and windy The father said *in evidence* that he had taken every precaution in preparing and warming the room into which his wife and baby were taken. On May 20 the baby was ill and a doctor ordered his removal to hospital where he died on May 22.

The mother said *in evidence that she* did not think that the child had on enough clothing when it was discharged The baby seemed cold when they arrived home A staff midwife said that she wrapped the baby in blankets, and thought it was sufficiently guarded against the weather Asked if she approved of a baby going out of hospital so soon after birth, the midwife said that this was due to the bed situation they could not do anything else It would be ideal, she said *if there* were bigger hospitals with better accommodation so that babies might be able to stay there for up to fourteen days.

Medical evidence was given that every precaution was taken with the child and that there was nothing unusual in discharging a healthy mother and child after two days

Summing up the coroner said *it might strike the jury* that once a decision to discharge the baby had been taken it was a [illegible] and had to go through You may feel there is some lack of cohesion, coordination, or supervision on the part of the hospital staff.

Returning a verdict of death from natural causes, the jury added a rider that the baby was sent out of hospital too soon and that the standing order operative in the obstetric ward of the hospital regarding the discharge of mothers and such young babies be made more elastic.

Newspaper's Account of an Operation

In January a newspaper published[13] an account of an operation performed by a thoracic surgeon at the Churchill Hospital Oxford The surgeon *objected* to this article which he had not in any way authorised He objected not only on the grounds of unwanted publicity for his name and the inaccuracies *in the article* but because he felt that the article might rouse unfair fears in the minds of patients who might believe that they suffered from a similar condition The Medical Defence Union accordingly instituted proceedings on his behalf against the newspaper, and its issue *of April 24* published a correction of the inaccuracies *and an apology* to the surgeon.

Coitus Interruptus

The recent case of Knott *v* Knott[8] raises again the troublesome question of how far the practice of coitus interruptus should be treated as a ground for dissolving a marriage It is necessary in this connection to distinguish clearly between nullity and divorce A decree of nullity may be obtained on the inability or wilful refusal of one of the spouses to consummate the marriage It is still not clear whether insistence by the husband on coitus interruptus amounts to non consummation In the leading case of Baxter *v* Baxter,[9] in which the House of Lords decided that insistence by the wife on the use of contraceptives did not amount to non consummation, the question of coitus interruptus was specifically left undecided Later that year (1948) Mr Justice Finnimore, in the case of Grimes (otherwise Edwards) *v* Grimes,[10] granted a decree of nullity on the ground that the practice of coitus interruptus contrary to the wife's wishes amounted to non consummation In a case decided only three days later—White (otherwise Berry) *v* White[10]—however, Mr Justice Willmer held exactly the opposite , coitus interruptus was not wilful refusal to consummate, although it might be legal cruelty if it resulted in injury to the wife's health

Mr Justice Willmer's decision was followed by Mr Justice Hodson in the case of Cackett (otherwise Trice) *v* Cackett (1950) His Lordship added that the court would be driven into an impossible position if it tried further to define what amounted to normal sexual intercourse between normally formed people , for, where a woman alleged that the man had failed to complete the sexual act, the court would have to inquire exactly at what stage emission took place or what degree of satisfaction was reached by the woman

There the position with regard to nullity remains Nevertheless, as suggested by both Mr Justice Willmer and Mr Justice Hodson in the cases just mentioned, a decree of divorce (as distinct from nullity) may be obtained on the ground of cruelty Legal cruelty has been defined as conduct of such a character as to have caused danger to life or limb or to bodily or mental health, or as to give rise to a reasonable apprehension of such danger A decree on the ground of coitus interruptus was in fact obtained in Walsham *v* Walsham (1949) , in that case the husband persisted in withholding full intercourse although warned by his wife and by doctors of the probable consequences for her health which did in fact ensue

The new case of Knott *v* Knott carries the matter a stage further, since in this case a divorce was granted although the husband had not been warned by doctors of the consequences likely to result to his wife

The husband and wife were married in 1942 when she was not quite 17 and he was 22 She was of a sensitive disposition, more liable than most people to be affected by events, and she greatly wanted to have a child The man was insensitive to the point of recklessness and did not want children After marriage they had no home of their own but lived with her parents , there were long separations due to the war, from which he returned in 1945 During the ensuing years the husband often acted in an aggressive manner towards the wife and there were quarrels between them In 1946 the wife was ill with tuberculosis In 1953 the husband left the wife, who refused to follow him and continued to live in her parents' home. Throughout substantially the whole period of the marriage he had refused full sexual intercourse and had practised coitus interruptus against her will He had not received advice from any doctor that the continuance of this practice would injure her health

Mr Justice Sachs held that the husband's conduct, viewed as a whole, amounted to cruelty , further, the refusal to allow the wife a child and the practice of coitus interruptus in disregard of whether it injured her health or not, coupled with the obvious injury to her health, amounted to cruelty even though he had not been warned by doctors of the potential results His Lordship said

> " I am not prepared to hold that his wife's deterioration in health was due to an active intent to injure his wife, *I do* hold that in determining to continue with coitus interruptus and in refusing to let his wife have children he was reckless of the effect on his wife and that his conduct was inexcusable
>
> I would hold that for a man deliberately and without good reason permanently to deny a wife who has a normally developed maternal instinct a fair opportunity to have even a single child is of itself cruelty when injury to herself results and when the husband adopts a course which preserves to himself a measure of sexual enjoyment "

Refusal to have a Child

In another recently decided case—Forbes *v* Forbes[11]—it was the husband who obtained the decree, it being held that the wife's conduct in refusing to have a child amounted to cruelty

The parties were married in 1945 , both were then about 26 Before the marriage the wife had never raised any objection to having children, and she knew that the husband was particularly fond of children After the marriage the wife insisted on the use of contraceptives , at first the husband reluctantly agreed to use them himself, but later the wife herself used them He attempted to persuade her to have a family, but she made various excuses and avoided discussing the subject as far as possible On occasions she taunted him about his desire for children By 1950, as a result of her refusal to have free intercourse, their relationship had become strained In February, 1953, the wife for the first time definitely refused to have children and in November, 1953, the parties separated By that time the husband was in a bad state of health as a result of her refusal to have children

Mr Commissioner Latey held that the wife's conduct had caused injury to the husband s mental health , her conduct was intentional in that she pursued it although she knew that her persistence was causing him anxiety and misery , accordingly she had been guilty of cruelty and the husband was entitled to a decree In the course of his judgment the learned commissioner said " Quite apart from the exhortation in the solemnisation of matrimony that, first, Christian marriage was ordained for the procreation of children, I cannot ignore the fact that it is a natural instinct in most married men to propagate the species and to bear the responsibilities and enjoy the comforts of their own children If a wife deliberately and consistently refuses to satisfy this natural and legitimate craving and the deprivation reduces the husband to despair and affects his mental health I entertain no doubt that she is guilty of cruelty

[7] Bowley C C Dunsford I *Lancet* 1954, ii 1050
[8] All England Law Reports 1955, vol 2 p 305
[9] See *Lancet* 1948 i, 38 225
[10] *Ibid* p 883
[11] All England Law Reports, 1955 vol 2, p 311

It would appear that these words are subject to the qualification that the wife s refusal must be without justification For as Lord Justice Denning has said

Where a man takes contraceptive measures against the will of his wife without reasonable excuse for so doing it is easy to infer that he does it with intent to inflict misery on her, but when a wife takes contraceptive measures or asks her husband to do so her conduct can often be attributed to fear of consequences to herself without any intention of injury to him In the present case however the wife was on record as saying that she had no fear of childbirth and the learned commissioner had no difficulty in finding that the wife s intentional acts amounted to cruelty

Baby Sent Out Too Soon?

An infant who was discharged from hospital two days after birth died five days later from pneumonia The inquest jury considered that the infant had been sent out too soon[12]

The baby was born on May 15 On May 17 the hospital told the father that his wife and the baby were to be sent home that evening They arrived home in an ambulance at 9 P.M on a night when it had been snowing and it was cold, wet, and windy The father said in evidence that he had taken every precaution in preparing and warming the room into which his wife and baby were taken. On May 20 the baby was ill and a doctor ordered his removal to hospital where he died on May 22.

The mother said in evidence that she did not think that the child had on enough clothing when it was discharged the baby seemed cold when they arrived home A staff midwife said that she wrapped the baby in blankets, and thought it was sufficiently guarded against the weather Asked if she approved of a baby *going out of hospital so soon* after birth, the midwife said that this was due to the bed situation they could not do anything else. It would be ideal she said if there were bigger hospitals with better accommodation so that babies might be able to stay there for up to fourteen days.

Medical evidence was given that every precaution was taken with the child and that there was nothing unusual in discharging a healthy mother and child after two days.

Summing up the coroner said it might strike the jury that once a decision to discharge the baby had been taken it was cast-iron and had to go through. You may feel there is some lack of cohesion, coördination or supervision on the part of the hospital staff.

Returning a verdict of death from natural causes, the jury added a rider that the baby was sent out of hospital too soon and that the standing order operative in the obstetric ward of the hospital regarding the discharge of mothers and such young babies be made more elastic

Newspaper's Account of an Operation

In January a newspaper published[13] an account of an operation performed by a thoracic surgeon at the Churchill Hospital Oxford The surgeon objected to this article which he had not in any way authorised He objected not only on the grounds of unwanted publicity for his name and the inaccuracies in the article, but because he felt that the article might rouse unfair hopes in the minds of patients who might believe that they suffered from a similar condition The Medical Defence Union accordingly instituted proceedings on his behalf against the newspaper and its issue of April 24 contained a correction of the inaccuracies and an apology to the surgeon.

In England Now

A Running Commentary by Peripatetic Correspondents

INTERLUDE

The water murmurs beside me murmurs ceaselessly
While I sit still, content
My moment taken out of the current of time
The dry stones of the rocky watercourse
Pale as bleached bones are silent as time past
While the water murmurs. Through these pared stone
Bones of the land laid bare the river flows
Deep through the narrows and spreads wide
Into a sheet of silken blue spread at my feet
Its satin smooth blueness frayed into purple
Into the rough purple splatches of shallows,
As I still sit stilled in the moment between
Past and present This is the moment of no momentum
Poised between memory of pleasure past
And foresight of delight.
So I sit relaxed caressed by the sun and teased
By an easterly breeze looking towards a steep hillside
Where tender green of the new grass and dusty pink of
full budded trees
Please my spring sap running senses. I see with approval
The sinuous strength of the tree that thrusts
Its dark twigs above me thrusts them into the sky
With their gleaming golden spear-sharp buds
Held high thrustingly overflowing with life And the water
murmurs
Under the cover of ceaseless plasheling rushing
Comes softly a lazy liquid gurgle
An undertone an aside of the lively river
Over the colour flickering lights of small wet boulders
Shine and signal their silent delights
While the water murmurs. And I sit still

* * *

This year we sought sunshine and warmth in Spain and, as by products our search brought us one mild adventure and one diagnostic triumph

The first began on a journey by bus to San Feliu: we were a willing audience to floods of abuse at the iniquitous charges of the bus from an elderly French couple and when in the evening we were taking tea on the pavement in the square they came up They were not going back in the *maudit* bus they had hired a boat would we share it? It had a motor oh yes! It would take only two and a half hours. Madame was the leader firm and masterful We agreed but when we saw the boat we realised that our friends were not only enterprising but intrepid The words of the Breton sailor's prayer came into my mind: O God my boat is so small and Thy sea is so large. However ashamed to jib we climbed in The sky was greying the wind rising the boat, overloaded with six adults (two crew) faltered at the start but after rounding the point chugged cheerfully along We hugged the forbidding coast Great cliffs towered above us Pine trees grew in clefts of the rock, almost to the water s edge We passed an occasional sandy beach at the foot of an olive grove caves, islets and one house perched on a height and finally hauled up in our own bay before the hated bus could have arrived

This led to our diagnostic triumph The French couple invited us to tea A Belgian lady came in distraught her son aged six, was very ill; he had developed a cough in the plane The Spanish doctor had seen him in the morning and had given an injection of penicillin but she could not understand what he had said about the diagnosis. Would the English physician tell her what was the matter with Alexander? I said doubtfully that I would try realising that the Spanish doctor had probably temporised for lack of evidence As I left the tea table my surgical colleague who can turn Centigrade to Fahrenheit in a trice murmured They say his temperature is 103 Luck was with me—the child would not cough there were no Koplik s spots but as I was percussing his chest I saw a faint incipient rash and plumped for measles.

I described the course of the illness outlined the routine, and left amid general satisfaction and relief with the words "he will begin to be better in three days" My own relief was quite as intense when I learnt that the disease had played the game

My morning paper comes from a northern city and is renowned for its clarity of thought and grace of expression It even found its way regularly to London, to my smug satisfaction, when the London papers failed recently for a period to appear

In a recent issue the last sentence in an article on Labour's likely investigations into its failure at the election read "The post-mortem will undoubtedly be long, thorough, and not painless" Although I am not in the way of writing to editors I could not resist dropping a note quoting this, and, with my tongue in my cheek and a large exclamation mark at the end, saying that the idea that a post-mortem could be painful might deter many people and their relatives from allowing autopsies I am not surprised that my letter was not published but a courteous assistant editor, a few days later, replied thanking me and pointing out that a post-mortem could cause pain to relatives

Wondering whether it was worth arguing with this undoubtedly highly educated party as to what was the difference between pain and mental distress, I happened to take up the issue of the paper for that day and there, quoting Mr Bevan from *Tribune* was the sentence "It is, perhaps, inevitable for a post-mortem to be held on Labour's defeat, but those who hasten to take part in it should keep in mind that it is a living body they are about to examine"

I do not think I will bother with journalists' or politicians' ideas of post-mortems any more

* * *

A somatotype of my acquaintance—a bit of an ectopene, actually—whom I met on the Heath while exercising our respective dogs, confessed to me that he had had great difficulty in remembering the physical and mental traits associated with the three standard types until he had related them to the canine world "whose characteristics," he added, "are so much better known to the average Englishman than those of his human associates Take a pug," he said, "a typical endomorph! His podgy physique, love of good food—stomach before sex is his motto—and insistence on postural ease and comfort would rate him as a 711 The peke, with his bland and tolerant outlook and love of polite ceremony—I quote the literature—is another endomorph, though I admit that, confronted with a rabbit, he becomes pretty mesomorphic The aggressiveness, the love of exercise, of action and even of combat, and the vehemence of expression (*Will* you stop barking, Spot!) mark the terriers as the supreme mesomorphs And the greyhounds, collies, and red setters, with their linear outlines and speedy mental and physical reactions, fall naturally into the ectomorphs" "Thank you," said I, "for these hints As a mesomorphic-ectomorphic-endomorph may I suggest that we now drop in to The Spaniards and have one?" "Willingly," he replied, "but meanwhile do not let us forget that there is an earlier and more elegant description of the type you have just mentioned, I mean, *l'homme moyen sensuel*"

* * *

News from School —"I gained six pounds (weight unfortunately) in the holidays Last night I attempted to ride a horse tethered in the Park The horse however did not want to be ridden so after giving it about 10*s* worth of sweets it kicked up various legs And this somewhat dismayed me, so I continued on my way to the dreadful Entertainment This was a Dutchman (Deutch) who could multiply 12 figure numbers together in his head In the end the headmaster asked him to answer any questions that 'the boys may put' He said No, I don t want to answer any questions, please may I go now?' The headmaster took no notice as the Dutchman had not a very good accent, so the headmaster repeated his request The Dutchman said 'Thees vaas not on ze programme,' however, he wrote a lot of figures on the blackboard and asked us if we understood We said that [illegible] and he rushed out"

Letters to the Editor

CHILDREN'S TEETH

SIR,—May I appeal to all medical practitioners, and through them to nurses and medical auxiliaries who have contact with children (and mothers), to emphasise the necessity of regular dental inspection and early treatment? The increasing number of cases where teeth of the permanent dentition are lost prematurely is appalling. We are creating daily more orthodontic and dental problems than our undermanned dental profession can hope to deal with One wonders whether our educational system is lacking Should not more attention be paid to teaching oral hygiene in the schools, since in many homes the parents are too ignorant or too apathetic to take an interest in their children?

When many of the present day school children become parents the whole sorry story will be repeated Last year the British Dental Association presented a memorandum on child dental health to the Ministries of Health and Education, and it is to be deplored that the medical press have not seen fit to publish a résumé of this important document

Prevention is the important aspect of the problem because owing to an increasing shortage of dentists we cannot give adequate treatment to all classes The priority classes should, of course, have preference, but, pending national arrangements to secure adequate treatment of children, let us try to attack the problem by attention to diet and hygiene

Selly Oak Hospital,

PSYCHOSOMATIC DISEASES IN UNDERDEVELOPED AREAS

SIR,—Osler's remark that "As clinicians we observ the experiments of Nature," would seem to apply on grand scale to Professor Davidson's observations (April 2 on the incidence of those diseases which are commonl called "psychosomatic" The evidence which he present in his letter is of importance to all concerned with th problem of the ætiology of rheumatoid arthritis As ou findings here are somewhat similar to his own, they ma be of interest to others working in the same field, as wel as to politicians and health authorities engaged in th development of "underdeveloped areas"

In the Queen Elizabeth Hospital for Rheumatic Diseases, which is situated in a district with a large Maor population, we see very few Maori patients with rheumatoid arthritis In the past year I have seen only 3 and it may be significant that all of them were eithe married to Pakehas, or had a history of previous neisserian infection, or both The rarity of rheumatoi arthritis, and of other diseases commonly called "psychosomatic," amongst Maoris (in the areas away from th two largest cities in the North Island of New Zealand, is confirmed by several general practitioners with whom I have spoken, so that I am not inclined to think that my experience, based on hospital cases, is unrepresentative

Hitherto it has not been easy to decide whether to attribute this great difference in incidence to genetic or to environmental factors Now, in the light of Professor Davidson's observations, it would appear that environmental factors would be a more likely explanation than a genetically determined racial immunity

He raises the question of the relative importance of metabolic and emotional factors in the ætiology of these disorder Here one is on very uncertain ground, but emotional factors would appear to be frequently operative in initiating the abnormal metabolic processes involved Our experience of rheumatoid arthritis in patients here accords very well with that of Professor Hartfall[1] who found associated emotional disturbance in 68% of his series According to Halliday[2] one of the hallmarks of diseases of emotional origin is a tendency for the peak incidence to shift to an earlier age group and for the severity to increase, with continual failure of adaptation to environmental pressure The observations of the distinguished physicians mentioned in Professor Davidson s letter could therefore be interpreted as supporting an emotional ætiology

The Maori population is not as yet reacting with the same type of emotional disturbance possibly because their culture is less competitive and because they are less exposed to "social isolation, especially when compared with Pakeha immigrants This does not mean that the Maoris are immune from emotional disturbance but only that it takes different forms The present risk is that, in freeing themselves from the danger of psychosomatic death following infringement of a taboo they may become more liable to peptic ulcers and to rheumatoid arthritis

As it has taken less than forty years for this change to occur in the United States of America it is of some importance to public-health administrators to know how to prevent a parallel change elsewhere without sacrificing a high material living standard In this respect it has been shown by LeCorbusier that it is not by any means necessary for a materially advanced culture either to cut itself off from the basic rhythms of nature, or to split itself up into a disintegrated state of individual social isolation, as is the present trend These last remarks apply to the development of developed areas, but in dealing with undeveloped ' areas they might do worse than consult the UNESCO handbook *Cultural Patterns and Technical Change*[3] Consultation with a cultural anthropologist before initiating any major changes such as housing schemes in new factory areas could prevent major social disintegration even if the Corbusian dream remains long unrealised.

HYPERSENSITIVITY ANGIITIS

SIR,—In their article of June 4 Dr Edge and his colleagues describe a case of polyarteritis which followed a typical and mainly progressive course, starting with lesions of the respiratory tract and ending with glomerular involvement and renal failure The patient was treated successively with penicillin streptomycin isoniazid and cortisone. They suggest that hypersensitivity to penicillin caused the disease and that hypersensitivity to the other drugs aggravated it

The theory that drug hypersensitivity can cause or aggravate polyarteritis is, except in the case of thiouracil founded largely on observations of this sort. Such evidence is unconvincing for two reasons Firstly it is possible that the initial condition for which the drug was given may have been polyarteritis and not a simple infection Secondly even in the absence of any treatment the disease is liable to repeated exacerbations it is therefore to be expected that the giving of drugs may often by pure coincidence be followed by deterioration

In the present case, the authors date the onset of polyarteritis from the appearance of a skin rash and lung lesions, regarding the ' otitis media ' which preceded these as a simple infection. But experience strongly suggests that the otitis media in this case was due to specific granulomatous lesions and was thus a part of the polyarteritic illness. This is a not uncommon presentation in cases of polyarteritis with lung involvement. If this view is correct then clearly the penicillin treatment of the ear condition did not cause the polyarteritis During the *subsequent course* of the disease the association between drug treatments and exacerbations of polyarteritis was no more than could be readily explained by chance To infer a causal relation from such evidence is only to confuse our understanding of the disease, especially when the postulated causes are multiple

Dr Edge and his colleagues *go on to argue* that corticotrophin should be used rather than cortisone in the treatment of the disease. Their opinion is based firstly on reports of polyarteritis occurring in cases of rheumatoid arthritis treated with cortisone and secondly on the observation of Rich and his co workers of a peculiar form of glomerulitis in sensitised rabbits treated with cortisone. The first observation must be interpreted with caution since rheumatoid arthritis quite commonly precedes polyarteritis even in the absence of cortisone therapy and in the second instance it *is unjustifiable* to identify the experimental lesions with human polyarteritis Cortisone has been used extensively in the treatment of polyarteritis, and I have personally had access (mostly through the Medical Research Council) to over 40 such cases without finding any evidence of its causing either hypersensitivity or renal damage. In adequate dosage (which may mean 500 mg daily or even more) it prevents the appearance of new lesions in nearly all cases In these circumstances it seems reasonable to continue to use this form of treatment –

GEOFFREY ROSE.

LUNG CANCER IN ASBESTOSIS

SIR,—In your annotation of June 4 the final sentence poses an important question The dust diseases generally act on the connective tissues and there is no satisfactory explanation of why the asbestos fibres should affect the epithelium as well '

The answer to this problem may well be found in a consideration of the histology of human asbestosis. The essential pathological lesion in asbestosis is a fibrosis around the respiratory bronchiole with thickening of alveolar walls and included asbestosis bodies Asbestosis bodies are found in the respiratory bronchioles and alveoli as well as interstitially There is evidence to show that asbestosis is initiated by the inhalation of fibres whose length is between 20 and 50 microns[1] The flexibility of such a fibre enables it to reach the respiratory bronchiole but its size renders removal by phagocytes difficult or impossible Small asbestos particles and fibres under 5 microns can be engulfed by phagocytes and removed by lymphatic channels or dissolved in tissue fluids. Many long fibres penetrate the bronchiolar and alveolar walls, while others go through their characteristic changes in these epithelially lined spaces. As the pathological changes become more advanced there is much thickening of alveolar walls with imprisoned clumps ' of asbestosis bodies

Gloyne stated[2] When the diffuse fibrosis has reached an advanced stage all alveoli in the area may be compressed out of recognition. Here surely we have an environment which allows chronic irritation by a fibrous mineral to epithelium This irritation reacts on the epithelium in circumstances of increasing abnormality The asbestosis body moreover is undergoing slow changes well described by Gloyne[2] which ultimately result in its disintegration With the increasing fibrotic condition of the involved areas there is a possibility of a chemical effect on the tissues from the solution of the bodies in these abnormal conditions

In view of these facts there would seem to be no lack of opportunity for the asbestos fibre and bodies form from fibres or chemical material produced by the disintegration of bodies, to affect epithelial structures in the lungs

CYCLICAL VOMITING

SIR,—The letter of Dr Millichap in your issue of Feb 19, commenting on Dr Wallis's paper (Jan 8), and Dr Wallis's subsequent letter (Feb 26), gives the impression that most or all cases of cyclical vomiting are epileptic in origin Some may be, but, lest all children who have the disorder be stigmatised as having epilepsy, accurate diagnosis is important It should be pointed out that in certain cases, at least, no evidence of epilepsy is present The disorder may recur in uniform episodes with remarkably regular periodicity for years, which is not characteristic of epilepsy In some patients, cyclical vomiting persists or recurs in adult life in a different recurrent form Such patients I regarded as having one of the bizarre forms of periodic disease of unknown cause[1]

PROTEINURIA

SIR,—The work of Greiner and Henry,[2] to which you referred on June 4, may throw light not only on the mechanism of postural proteinuria but also on that of proteinuria in heart failure

On the basis of their own investigation and that of Farber et al,[3] Greiner and Henry criticise the view[4] that postural proteinuria is due to increased renal venous pressure causing passive congestion of the kidneys They refer to the work of Pappenheimer[5] and suggest, with regard to the intrarenal mechanism, that postural proteinuria is due to slowing of the glomerular blood flow, resulting in an abnormal glomerular filtration of albumin, and to decreased tubular resorption of the protein in the glomerular filtrate They attribute both factors to renal arterial vasoconstriction

It is at present generally held that proteinuria in congestive heart-failure is due to passive venous congestion of the kidneys resulting from failure of the right ventricle This view is based on the "back-pressure" concept of heart failure I have presented evidence, however, showing that proteinuria may result from left ventricular failure, and indicating that proteinuria in biventricular congestive failure is due to the failure of the left ventricle[6] My findings appear to support the "forward-failure" concept of heart failure, and perhaps signify that the mechanism of proteinuria is similar to that suggested by Greiner and Henry for postural proteinuria

This possibility is strengthened by the occurrence, in postural proteinuria and in congestive heart-failure with a low or normal cardiac output, of certain other features in common, in addition to the protein in the urine These are a decreased circulation rate, stasis of blood in the legs, and oliguria On the other hand, in congestive heart-failure with a high cardiac output, in which the circulation rate and rate of blood flow in the legs may be normal or increased, proteinuria[7,8] and oliguria[9] may be absent

THE ACTION OF CHLORPROMAZINE

SIR,—I am glad that Professor Samson Wright (April 2) has given his opinion a priori on the "phenomena of Reilly" this letter showed how far removed the experimental facts are from traditional physiology, and therefore justified the importance we have for a considerable time attached to this study His letter also showed the need to add a few complementary details, the development of which can be found in the works referred to by Dr Buxton Hopkin (March 19)

I have suggested that the expression "phenomena of Reilly" should include all non-specific disturbances attributable to aggression of very different kinds (chemical, physical, bacterial, &c), and I proposed this as a mark of respect to the chief of the school who, following others, undertook this study and who has done most to define these phenomena more precisely, to show their importance in the pathogenesis of many illnesses, and to indicate the primary rôle of the visceral nervous system in their development[1]

Non specific phenomena have been the subject of a great many researches in the past sixty years At the beginning of this century the non specific reaction of the adrenal cortex and medulla had been particularly implicated[2] The part played by the nervous system in these disturbances assumed more importance following the work of such people as Ricker in Germany, and Speransky in Russia But it was Reilly and his collaborators who supplied most details in this connection, and who definitely showed the importance of the irritation of visceral nerves

The experimental facts revealed by the Reilly school have been confirmed subsequently by so many authors that there is no longer any point in confirming them, as Professor Samson Wright suggests Any research-worker can easily reproduce them in any laboratory It would certainly be useful, as Dr Hopkin suggests, to study in Anglo Saxon countries these phenomena whose recognition represents in our eyes one of the most important discoveries of biology and medicine in the past thirty years, but which still remain very mysterious from several points of view One can only quote in this respect the works of Selye The "reaction of alarm," subsequently described by Selye, is in fact the same as the phenomena described earlier by French workers But his pathogenic concept is directly connected with the old suprarenal theory held in France at the beginning of this century[2] The insufficiency of this theory now seems to us to have been well established and I have indicated elsewhere, on the basis of precise and confirmed experimental facts, that the "general syndrome of adaption" does not exist[3]

Professor Samson Wright is justified when he says that the experimental facts revealed by Reilly and his collaborators are unexpected to a physiologist I have already insisted on the importance of this fact and I must emphasise that I proposed the expression "*phenomena* of Reilly" because in my opinion there are two separate groups of fundamentally different phenomena, which it has for long been difficult to differentiate since they often appear to be confused

(*a*) Adaptive reactions, normal and pathological, which are in the category studied by traditional physiology

(*b*) Cellular disturbances, more or less prolonged and whose histological and clinical sequelæ may only appear after a very long latent period These may escape the laws of classic physiology and that is why I have distinguished them by the name "neuxenic phenomena" from phenomena responding to the classic laws from which they have not yet been isolated. They often appear a long time after the aggression which caused them and they can be noticed normally only when the laboratory animals are observed for a long period and are operated on under very stringent aseptic conditions (especially as they habitually show a fall in general immunity) Neither of these conditions is generally observed in the common run of physiological research Furthermore, neuxenic phenomena respond to special biological laws, in which the laws of probability play a notable part, having an importance

---

1 Decourt, P Phénomènes de Reilly et syndrome général d adaptation de Selye Paris 1951
2 Decourt P *Pr méd* 1952, 60 663
3 Decourt P *Ibid* p 1028

comparable with the quantitative laws which represent one of the most important discoveries of the atomic physicists

It is these neuxenic phenomena—which comprise only a part of the phenomena of Reilly but which play an important rôle in pathology—that have truly baffled on the one hand all attempts at an explanation of the phenomena of Reilly in terms of conventional physiological thought[4] and on the other hand the numerous efforts made over the last twenty years to prevent them.

The researches of the school of Reilly have above all been devoted to works of 'pure science but they have nevertheless had happy consequences in applied science. In effect it was the studies on the pathogenesis of the phenomena of Reilly and the efforts to prevent them which beginning in 1935 led to the discovery of antihistamine therapy in 1941 and to narcobiotic therapy in 1951 The results obtained were indeed negative with the antihistamines and that is why when I published the first results of antihistamine therapy in man in 1942 I did not speak on that occasion of phenomena of Reilly which had been the starting point of our research[5] Reilly has himself emphasised that it was in 1952 after seventeen years' research that it was at last possible to exert an effect on the phenomena, thanks to chlorpromazine But these results are still very inadequate I fear indeed that from their very nature no therapeutic procedures can ever completely prevent the neuxenic phenomena which represent the most serious disorder of the phenomena of Reilly We can however hope to improve the methods of preventing them

Paris. PHILIPPE DECOURT

CHLORPROMAZINE AND EPILEPSY

SIR,—The occurrence of convulsions during treatment with chlorpromazine has been reported recently in two papers in your columns.[6] [7]

A few months ago a seizure was observed in an epileptic patient attending an outpatient clinic of this hospital who had been free from fits for 2 years and had been given chlorpromazine by mouth for a few weeks. The convulsion occurred during photic stimulation in the course of a routine E.E.G examination. This observation suggested an investigation into the effect of chlorpromazine on the E.E.G of epileptics

So far fourteen epileptic patients have been examined After a routine E.E.G including overbreathing and photic stimulation, an intravenous injection of chlorpromazine is given (1 ml. [25 mg] diluted to 10 ml with normal saline) The amounts vary from 7 mg for a child to 25 mg for an adult The injection is given slowly 1–2 ml. (5–5 mg) every 1–2 minutes.

In seven cases no specific changes have been seen These patients had never shown grossly abnormal inter-seizure recordings. In the other seven cases the previously observed abnormal features increased but no new abnormal phenomena were seen. Thus in a child of 10 with clinical petit mal and typical 3 c/s spike-and wave attacks, the attacks increased in duration from 2–3 to 25–110 seconds in a woman of 35 generalised symmetrical multiple spike and slow wave bursts increased from one every 5–10 minutes to one every 5–30 seconds; in a man of 61 bilaterally synchronous and symmetrical 2–3 c/s slow wave runs increased from one every 15–60 seconds to one every 5–10 seconds in a man of 68 with left-sided anterior temporal focal spikes the increase was from 1 spike every 5–10 seconds to one every 2–3 seconds

In each group of seven one patient was without anticonvulsants, and the other six were on their usual medication.

The effect of chlorpromazine becomes noticeable within about 15 minutes It appears to run roughly parallel with the oncoming drowsiness.

The findings suggest that chlorpromazine by the intravenous route can increase the abnormal epileptic' activity of the brain as seen in the E.E.G They suggest that caution may be advisable in treating epileptic patients with the drug

A detailed report of the investigations with special regard to the use of chlorpromazine as a stimulating agent in E.E.G work will be published elsewhere

Mapperley Hospital,
Nottingham WALTER FABISCH

HEROIN

SIR,—Your editorial statement after Mr Southwood's letter of June 11 suggests that unless the manufacture of heroin is prohibited in this country the success of efforts to deal with addiction elsewhere would be prejudiced Such a ban can help to control addiction only if heroin legitimately made in Britain is getting illicitly into the hands of addicts No evidence that this is happening has been nor is it likely to be, produced Surely the medical profession are justified in demanding such evidence before accepting the limitation of liberty involved by the ban especially since Dr Wand in your report of his defence of the Government's action admits that it may lead to an increase in suffering however slight that may be.

In the United Nations publication *Bulletin on Narcotics* and in other United Nations documents, evidence may be found which leads to the conclusion that legally manufactured heroin supplies a negligible amount of the world's illicit traffic and that British sources supply none whatever Some other relevant facts and conclusions from the same sources are these

(1) The clandestine manufacture of heroin from opium and crude morphine is child's play' and such manufacture is an important source of illicit heroin

(2) As long as opium and morphine are available illicitly it will be impossible to control heroin production and addiction

(3) The U.S.A has recently suffered a serious exacerbation of heroin addiction affecting even school-children despite a ban on heroin now of thirty years standing The suggestion that results will appear only when the heroin ban is universal cannot be maintained in the light of the known facts on the sources of illicit heroin

(4) That the only way to abolish heroin addiction is to remove weaknesses in the control systems of opium producing countries which are at the root of the trouble

The main events leading to the present action may be summarised as follows

In 1924 a committee of the House of Representatives of the U.S.A. met to consider the heroin problem which was very serious then and since It was concluded that the medical use of heroin was negligible compared with its evil effects, and the drug was banned Since then international organisations have repeatedly toyed with the idea of a universal ban

At the 1931 Conference for the Limitation of the Manufacture of Narcotic Drugs at Geneva proposals to ban heroin entirely and to ban its export from producing countries were made The British delegate opposed both measures.

In 1954 at the 243rd meeting of the Commission on Narcotic Drugs a vote was taken on a proposal that all countries should be recommended to ban heroin The British delegate abstained because he had received no specific instructions; he was confident however that the United Kingdom would give the resolution favourable consideration. This has now been done but still the medical profession has been given no evidence that the ban will help the international problem

It might be suggested that we should support the United Nations and set a good example in this respect but it surely cannot be argued that to impose a useless prohibition which infringes medical liberty and may cause suffering would favourably impress anybody

The second part of the Government ban that on export will be beneficial in lessening opportunity for theft in transit and since heroin can be made so easily legitimate consumers overseas will not be deprived

---

[7] Lomas, J Boardman R. H Markowe M *Ibid* June 4 1955 p 1144

I suggest, Sir, that we should not, in fact, "prejudice the success" of the international effort to prevent heroin addiction "if we dissociate ourselves from it," and that "a few sufferers should be allowed a little extra suffering" (as Dr Wand suggests) only when evidence is produced showing that their suffering will lead to a greater good Until then it is to be hoped that the medical profession will continue to oppose this administrative ban

Loss of heroin in this country will be loss to patients not loss to addicts

LUNG CANCER AND SMOKING

SIR,—Mr Gould's comments (June 4) upon a relatively unimportant statistical test of significance that we used in our paper of three years ago should not be allowed to obscure the accumulated evidence upon the association between smoking and lung cancer Since 1950 there have been published the results of thirteen other similar inquiries, carried out in six countries, all but one of them have revealed a substantial excess of smokers among the patients with lung cancer compared with the control group, and all of them have shown a large excess of heavier smokers amongst the lung-cancer patients The evidence from these numerous retrospective inquiries has been well supported by the preliminary results of two prospective inquiries In short, whether or not one interprets the weight of evidence as denoting causation, it is impossible, in our view, to suggest that the association is not firmly established

In fact, the statistical argument employed by Mr Gould is incorrect The figures, the significance of which he questions, are

	No of men with lung cancer	*No of men without lung cancer*
No of smokers	1350	1296
No of non-smokers	7	61

He argues that if N is the number of men from whom the lung cancer patients are drawn, p_1 is the proportion who smoke, and p_2 is the proportion who have lung cancer, then the expected number of lung cancer patients who smoke will be Np_1p_2 and the range within which the observed number is likely to lie will be $Np_1p_2 \pm \sqrt{Np_1p_2}$ With the figures he assumes for N, p_1, and p_2 (90,467, 0 975 and 0 015 respectively), he deduces that the expected number of smokers with lung cancer would be $1323 \pm \sqrt{1323}$—i e, would lie between 1287 and 1359 The error lies in his choice of formula for the standard deviation of a proportion. The formula $\sqrt{Np_1p_2}$ is a valid approximation to the standard error of the number of lung cancer patients who smoke, in an *unrestricted* random sample of N males (the approximation being valid because p_1p_2 is small) But we are concerned with the number of smokers found in a sample of 1357 lung cancer patients, and this has a standard error of $\sqrt{1357p_1(1-p_1)}$ This would agree with the previous formula if p_1 were small, since $1357 = Np_2$, but in fact p_1 is estimated as 0 975 The appropriate estimate of the range is, therefore, $1323 \pm \sqrt{(1357)(0\ 975)(0\ 025)}$ The observed number should, then, lie between 1317 and 1329 (though we would prefer to take limits of twice the standard deviation on either side of the expected number, giving 1311 and 1335)

The error would have become clear if Mr Gould had applied his formula to estimate the expected limits for the number of *non smokers* which might be observed by chance among the lung cancer cases He would then have found that the small number of non smokers was statistically highly significant A formula which gives different results when applied in two different ways to the same set of figures might reasonably be considered a trifle unconvincing

INVESTIGATION OF TONSILLECTOMY

SIR,—Your issue of June 4 (p 1184) referred to a proposed experiment approved by the South East Metropolitan Regional Hospital Board The same wording of this proposal has found its way into the local press "At Farnborough Hospital, Kent, and perhaps other hospitals in that area, 1000 children on the tonsils waiting list will be chosen for the trial 500 will have their tonsils removed and 500 will not The health of the two groups in the succeeding year will then be compared"

Farnborough Hospital is only one of several hospitals covered by the Bromley Group Hospital Management Committee, and the expression "in that area" leads both medical and lay public to assume that the consultant staff of these other hospitals may have agreed to such a plan, and, further, that this experiment would inevitably delay the admission of the 500 children in the control group, unless the waiting list were more than twelve months

The consultant staff of the Children's Hospital, Sydenham, would be glad if, through your columns, it could be made clear to practitioners in the area that no such inquiry is contemplated at this hospital, nor has the matter ever been referred to the medical staff committee, or to any individual member Since ethical considerations have been raised in the national press in connection with this proposed inquiry, it seems to us advisable to have the matter clarified in this way

Children's Hospital,
Sydenham, London, S E 26

D F ELLISON NASH
Senior Surgeon

*** Mr Ellison Nash's letter was shown to Dr Duncan Leys, whose name was quoted as being in charge of the investigation, and he replied

"Ethical considerations in this study differ in no way from those of other therapeutic trials If the value of the operation, which has a definite but undetermined morbidity, were unquestionable, there would be no need to undertake an investigation"—ED L

TUBERCULOSIS IN EIRE

SIR,—In your issue of June 11 (p 1221) you quote from an extremely interesting review of tuberculosis in Eire from 1949 to 1953 The figures show a very considerable increase in the number of patients treated, coupled with figures which show a very great fall in number of deaths

If the death-rate can be reduced to zero or nearly so, is it safe to say that tuberculosis has been eliminated from Eire? Surely with the figures being what they are in Eire, England, and Scotland, the measuring rod for tuberculosis should be amended so that the true criterion for tuberculosis is *not* the death-rate but the number of sick individuals

FOOD IN MENTAL HOSPITALS

SIR,—The mental hospitals have good reason to be grateful to the King Edward's Hospital Fund, and, as a member of a hospital management committee, I would like to congratulate the secretary of the Fund's hospital catering and diet committee on his article which you published last week

It is very true that large sums must be spent on equipment, and staff, before a civilised standard of catering can be reached in mental hospitals It is also true that an improvement well worth having can be made by spending even a few shillings per head more on food As little as 2*s* per head per week, spent on things that do not need cooking, such as milk, butter, cheese, fruit, salad, and marmalade, can make a very great difference

Even this modest sum involves an extra expenditure of £5200 a year on 1000 patients, and H M C members are timid about overspending

If the publicity you are giving to the disgracefully low standards that exist at the moment induces the [illegible] to feed the patients and damn the consequences I feel sure that the Treasury pig will be [illegible] to jump over the stile.

London, S.W.3 E. L. M. [illegible]

THE DIFFICULT APPENDIX

SIR,—I am grateful to Dr Horwitz (May 14) for drawing my attention to Dr Charles McBurney's original article[1] which has recently been made available to me through the courtesy of the librarian of the Royal Society of Medicine.

In 1940 Sir Hugh Devine[2] mentioned a position of the appendix in which it extends under the terminal part of the ileum and may give rise to "umbilical pain and other atypical symptoms." He went on: "anomalous forms of acute appendicitis, too, are most difficult to diagnose in their early stages and are the cause of many failures to make a prompt diagnosis." In abdominal diagnosis he reiterated the importance of a deep tender spot of visceral tenderness in localised inflammation, which is elicited by pressure of the finger point.

In 1937 Bowen[3] recommended palpating the iliac fossæ by trying to dip deep down on to the posterior abdominal wall with the fingers bent on the hand. He found that the local [illegible] pain usually at or about McBurney's point. "In rare cases local tenderness and resistance are entirely absent anteriorly in the lumbar region and on pelvic examination. In one case of which I have notes, the appendix was in a fossa behind the mesentery where it was securely hidden from prying hands."

In 1948 Sir Zachary Cope[4] warned against temporising and recommended always to make a very thorough attempt to elucidate the problem when the patient is seen for the first time. "It is only by thorough examination that one can propound a diagnosis, and if the early stages of the disease are to be recognised note must be taken of the earliest symptoms."

He recorded that if the appendix be situated behind the cæcum, or behind the end of the ileum and common mesentery, the inflammatory process will be somewhat masked by the gut lying in front. The place where deep tenderness can almost always be elicited is the spot just below the middle of a line joining the anterior superior iliac spine and the umbilicus. This roughly corresponds with the base of the appendix. Tenderness over McBurney's spot is not so constant. This tenderness appears to be localised actually in the appendix itself for the site of the pain varies somewhat according to the position of the appendix.

In 1889 Dr McBurney published 8 cases illustrating the new and successful treatment of early removal of the inflamed appendix. "All will acknowledge that every case of appendicitis may, so far as the cleverest observer can tell, have to pass many very dangerous obstacles before reaching the smooth water of a comfortable abscess. For my part, I would endeavour to ensure safety early before reaching the rapids rather than trust to finding my way blindfolded through a dangerous passage." His case 7 was tethered retro-mesenteric followed by temporary ileus.

He indicated the site of the greatest pain, determined by the pressure of one finger, as between 1½ in. and 2 in. from the anterior spinous process of the ilium towards the umbilicus. "No one will dispute that if we could so improve our methods of diagnosis that we could recognize within the first few hours the serious nature of many cases, we would operate in these cases at once, willingly preferring to incur the risks of an operation rather than face the certainty of death from septic peritonitis. How may we improve our methods of diagnosis? At present I see no clearer road than the exploratory incision permitting a direct inspection of the parts and a complete study of the disease."

No reference was made to the literature in my article of April 9 which recorded local experience of early acute appendicitis in its various forms and physiological manifestations, with appropriate deep tender spots. These are grouped in the form of a square each 1½ in. from Zachary Cope's spot which is just below the middle of a line joining the anterior superior iliac spine and the umbilicus. The lower right hand corner of the square [illegible] of appendix abscess but this is a complication [illegible] not included. The picture is completed by the outlying spots which are described.

The chronological analysis of the symptoms and signs [illegible] cases illustrating the stages of inflammation of the [illegible] end retro-mesenteric appendix revealed the [illegible] of the subileal deep tender spot and of the vertical line above this spot which is halfway between Zachary Cope's spot and the umbilicus. Deep tender spots indicating subileal spread of peritonitis are also indicated. Congenital retro-mesenteric tethering appears to account for the successive occurrence of severe appendicitis with ileus in several members of one family.

The seat of the greatest pain determined by the pressure of one finger must remain a cardinal point in diagnosis.

Obituary

REGINALD LANGDON LANGDON-DOWN

M.A., M.B. Camb.

AMONG medical families and traditions the Langdon Downs of Normansfield hold an honoured place. For three generations they have been responsible for this home for mentally defective children, and as its medical superintendent for some forty years Reginald Langdon Down, the senior representative of the second generation, made a considerable contribution to the scientific understanding and humane treatment of mental defect.

His father, J. L. H. Langdon Down, F.R.C.P., came up from Devonshire to study medicine at the London Hospital, where he eventually joined the staff. In 1868, with the help of his wife, he founded Normansfield as a home where mental defectives would be treated as members of a family. He allocated each small group of patients to the care of a single nurse who slept in their room. This system was successfully continued at Normansfield until recently. From small beginnings the home grew till it was able to accommodate 200 patients, and with it grew its founder's reputation. He was the first to recognise and name mongolism, which is known in Russia as "Langdon Down's disease."

Reginald was born in 1866, and from Harrow he went to Trinity College, Cambridge, where he took a first class in the natural sciences tripos in 1888. He continued his medical studies at the London Hospital, qualifying in 1892. After serving as an assistant demonstrator of anatomy and a house-physician at the London he took the M.R.C.P. in 1894 and settled in private practice in Teddington. He was already drawn to the family specialty and two years later on the death of his father he and his brother Percival took over Normansfield. He continued the tradition of a family relationship with the patients in which the staff share. Later when Normansfield became a limited company he insisted on resigning his M.R.C.P., though to the regret of his colleagues. Today the home is part of the National Health Service

I suggest, Sir, that we should not, in fact, "prejudice the success" of the international effort to prevent heroin addiction "if we dissociate ourselves from it," and that "a few sufferers should be allowed a little extra suffering" (as Dr Wand suggests) only when evidence is produced showing that their suffering will lead to a greater good Until then it is to be hoped that the medical profession will continue to oppose this administrative ban

Loss of heroin in this country will be loss to patients not loss to addicts

LUNG CANCER AND SMOKING

SIR,—Mr Gould's comments (June 4) upon a relatively unimportant statistical test of significance that we used in our paper of three years ago should not be allowed to obscure the accumulated evidence upon the association between smoking and lung cancer Since 1950 there have been published the results of thirteen other similar inquiries, carried out in six countries, all but one of them have revealed a substantial excess of smokers among the patients with lung cancer compared with the control group, and all of them have shown a large excess of heavier smokers amongst the lung cancer patients The evidence from these numerous retrospective inquiries has been well supported by the preliminary results of two prospective inquiries In short, whether or not one interprets the weight of evidence as denoting causation, it is impossible, in our view, to suggest that the association is not firmly established

In fact, the statistical argument employed by Mr Gould is incorrect The figures, the significance of which he questions, are

	No of men with lung cancer	*No of men without lung cancer*
No of smokers	1350	1296
No of non smokers	7	61

He argues that if N is the number of men from whom the lung cancer patients are drawn, p_1 is the proportion who smoke, and p_2 is the proportion who have lung cancer, then the expected number of lung cancer patients who smoke will be Np_1p_2 and the range within which the observed number is likely to lie will be $Np_1p_2 \pm \sqrt{Np_1p_2}$ With the figures he assumes for N, p_1, and p_2 (90,467, 0 975 and 0 015 respectively), he deduces that the expected number of smokers with lung cancer would be $1323 \pm \sqrt{1323}$—i e, would lie between 1287 and 1359 The error lies in his choice of formula for the standard deviation of a proportion The formula $\sqrt{Np_1p_2}$ is a valid approximation to the standard error of the number of lung cancer patients who smoke, in an *unrestricted* random sample of N males (the approximation being valid because p_1p_2 is small) But we are concerned with the number of smokers found in a sample of 1357 lung cancer patients, and this has a standard error of $\sqrt{1357p_1(1-p_1)}$ This would agree with the previous formula if p_1 were small, since $1357 = Np_2$, but in fact p_1 is estimated as 0 975 The appropriate estimate of the range is therefore, $1323 \pm \sqrt{(1357)(0\ 975)(0\ 025)}$ The observed number should, then, lie between 1317 and 1329 (though we would prefer to take limits of twice the standard deviation on either side of the expected number, giving 1311 and 1335)

The error would have become clear if Mr Gould had applied his formula to estimate the expected limits for t ber of *non smokers* which might be observed by ong the lung cancer cases He would then have the small number of non smokers was statis- ally significant A formula which gives different en applied in two different ways to the same set might reasonably be considered a trifle cing

THE DIFFICULT APPENDIX

SIR,—I am grateful to Dr Horwitz (May 14) for drawing my attention to Dr Charles McBurney's original article[1] which has recently been made available to me through the courtesy of the librarian of the Royal Society of Medicine.

In 1940 Sir Hugh Devine[2] mentioned a position of the appendix in which it extends under the terminal part of the ileum and may give rise to umbilical pain and other atypical symptoms. He went on: "anomalous forms of acute appendicitis too are most difficult to diagnose in their early stages, and are the cause of many failures to make a prompt diagnosis." In abdominal diagnosis he reiterated the importance of a deep tender spot of visceral tenderness in localised inflammation which is elicited by pressure of the finger point.

In 1937 Bowen[3] recommended palpating the iliac fossae by trying to dip deep down on to the posterior abdominal wall with the fingers bent on the hand. He found that the local right-sided pain usually at or about McBurney's point. In rare cases local tenderness and resistance are entirely absent anteriorly in the lumbar region and on pelvic examination. In one case of which I have notes the appendix was in a fossa behind the mesentery where it was securely hidden from prying hands.

In 1928 Sir Zachary Cope[4] warned against temporising and recommended always to make a very thorough attempt to elucidate the problem when the patient is seen for the first time. "It is only by thorough examination that one can propound a diagnosis, and if the early stages of the disease are to be recognised note must be taken of the earliest symptoms."

He recorded that if the appendix be situated behind the cæcum, or behind the end of the ileum and common mesentery "the inflammatory process will be somewhat masked by the gut lying in front. The place where deep tenderness can almost always be elicited is the spot just below the middle of a line joining the anterior superior iliac spine and the umbilicus. This roughly corresponds with the base of the appendix. Tenderness over McBurney's spot is not so constant. This tenderness appears to be localised actually in the appendix itself for the site of the pain varies somewhat according to the position of the appendix."

In 1889 Dr McBurney published 8 cases illustrating the new and successful treatment of early removal of the inflamed appendix. "All will acknowledge that every case of appendicitis may so far as the cleverest observer can tell, have to pass many very dangerous obstacles before reaching the smooth water of a comfortable abscess. For my part, I would endeavour to ensure safety early before reaching the rapids rather than trust to finding my way blindfolded through a dangerous passage." His case 7 was tethered retro-mesenteric followed by temporary ileus.

He indicated the site of the greatest pain determined by the pressure of one finger as between 1½ in. and 2 in. from the anterior spinous process of the ilium towards the umbilicus. "No one will dispute that if we could so improve our methods of diagnosis that we could recognize within the first few hours the serious nature of many cases we would operate in these cases at once, willingly preferring to incur the risks of an operation rather than face the certainty of death from septic peritonitis. How may we improve our methods of diagnosis? At present I see no clearer road than the exploratory incision permitting a direct inspection of the parts and a complete study of the disease."

No reference was made to the literature in my article of April 9 which recorded local experience of early acute appendicitis in its various forms and physiological manifestations with appropriate deep tender spots. These are grouped in the form of a square each 1½ in. from Zachary Cope's spot, which is just below the middle of a line joining the anterior superior iliac spine and the umbilicus. The lower right-hand corner of the square is the site of appendix abscess, but this is a complication which was not included. The picture is completed by two outlying spots which are described.

The chronological analysis of the symptoms and signs in the 7 cases illustrating the stages of inflammation of the tethered retro-mesenteric appendix revealed the constancy of the subileal deep tender spot and of the vertical line above this spot which is halfway between Zachary Cope's spot and the umbilicus. Deep tender spots indicating subileal spread of peritonitis are also indicated. Congenital retro-mesenteric tethering appears to account for the successive occurrence of severe appendicitis with ileus in several members of one family.

"The seat of the greatest pain determined by the pressure of one finger" must remain a cardinal point in diagnosis.

Obituary

REGINALD LANGDON LANGDON-DOWN

M.A., M.B. Camb.

AMONG medical families and traditions the Langdon-Downs of Normansfield hold an honoured place. For three generations they have been responsible for this home for mentally defective children, and as its medical superintendent for some forty years Reginald Langdon-Down, the senior representative of the second generation, made a considerable contribution to the scientific understanding and humane treatment of mental defect.

His father, J. L. H. Langdon Down, F.R.C.P., came up from Devonshire to study medicine at the London Hospital, where he eventually joined the staff. In 1868, with the help of his wife, he founded Normansfield as a home where mental defectives would be treated as members of a family. He allocated each small group of patients to the care of a single nurse, who slept in their room. This system was successfully continued at Normansfield until recently. From small beginnings the home grew till it was able to accommodate 200 patients, and with it grew its founder's reputation. He was the first to recognise and name mongolism, which is known in Russia as "Langdon Down's disease."

Reginald was born in 1866, and from Harrow he went to Trinity College, Cambridge, where he took a first class in the natural sciences tripos in 1888. He continued his medical studies at the London Hospital, qualifying in 1892. After serving as an assistant demonstrator of anatomy and a house-physician at the London he took the M.R.C.P. in 1894, and settled in private practice in Teddington. He was already drawn to the family specialty, and two years later on the death of his father he and his brother Percival took over Normansfield. He continued the tradition of a family relationship with the patients, in which the staff share. Later when Normansfield became a limited company he insisted on resigning his M.R.C.P., though to the regret of his colleagues. Today the home is part of the National Health Service.

but the family tradition continues and the superintendent is a nephew, Dr Norman Langdon-Down

Langdon-Down was a man of lucid and analytical mind with corresponding powers of expression He confined his considerable abilities within a limited field, and did all that he did well and graciously Many of his outside interests were closely linked with his specialty He was drawn into the inner counsels of the British Medical Association as an adviser on the evidence to be submitted to the Royal Commission on Lunacy Law and Mental Disorder, and he presided over a committee set up to study psycho-analysis, and served on the Central Ethical Committee His services were recognised by election as a vice-president of the association For many years he was physician to the National Association for the Welfare of the Feeble-minded, and by his work as chairman of the governors of Hampton Grammar School and as a governor of Epsom College he showed that he understood the needs of normal as well as defective children He was an acknowledged expert on Oriental porcelain, pottery, and furniture, and was himself a keen painter in water-colours

Dr Langdon-Down's first wife died in 1917 Five years later he married again, and his second wife died in 1942 He leaves two sons and two daughters He died on May 29 at the home which he shared with his daughter and son-in-law, Sir Russell Brain

JOHN EVERIDGE

O B E , F R C S

Mr John Everidge, consulting urological surgeon to King's College Hospital, died at his home in London on June 8

From King's College School he went to study medicine at King's College Hospital, qualifying in 1908 When he gained his F R C S in 1912, he was the youngest fellow He held resident appointments and the Sambrooke surgical registrarship at King's before he joined the R A M C in 1914 During the war he served with distinction as a surgical specialist, with the rank of major, and was mentioned in despatches and appointed O B E Soon after demobilisation, in 1919, he was appointed to the honorary staff of King's College Hospital as assistant urologist

On the retirement of Sir John Thomson-Walker in 1929, he was appointed senior urologist and gave up general surgery, which was at that time linked with the junior urological appointment, but he did not give up his interest in general surgery

He was consulting urologist to Queen Alexandra Hospital, Millbank, and he worked at many smaller hospitals, including the Sutton and Cheam Hospital and the Carshalton War Memorial Hospital He was one of the original consultants appointed to London County Council hospitals In the late war he was one of the senior staff at the Horton Emergency Hospital

Mr Everidge was long a prominent member of the urological section of the Royal Society of Medicine and he served as president during the early part of the late war He was a founder member of the British Association of Urological Surgeons, of which he later became hon treasurer, but his slight deafness made him refuse the presidency

J G Y-B writes "At King's Everidge's splendid teaching, imparted with wit without crudity, attracted large throngs to his clinics In surgery he was a pioneer in transurethral prostatic surgery as long ago as 1927, and played a part in the development of the modern resectoscope Always helpful to his juniors, it was a matter of pride to him that so many of his old house-surgeons held consultant posts His charm was outstanding and he was held in the highest esteem by his colleagues and friends, patients were devoted to him by virtue of his sympathy

"Outside his work he had many interests—lawn tennis in his early days, and in more recent years golf at Epsom and Deal, while many weekends were spent fishing with urologist friends He was a member of the Flyfishers' Club He always remained young, in surgery by keeping up to date with new procedures, and in private life by his enjoyment of all student activities, dances, and fast cars His after-dinner speeches were polished and entertaining He will be greatly missed as a surgeon and as a friend"

His wife was formerly Miss Kathleen Robertson, and he leaves a son and a daughter

ROBERT ARTHUR LYSTER

M D Birm , B Sc. Lond & Birm

During the first quarter of this century Robert Lyster's name was prominent among the planners of the personal health services, particularly the school medical service, and his colleagues, especially those of the older generation, will learn with regret of his death at the age of 82 at his home in Bournemouth

He began his studies at Mason College, Birmingham, taking the B SC Lond with double honours in 1893 He went on to study medicine at Queen's College and at Birmingham University, qualifying in 1900 He was early drawn to preventive medicine, and he held various lectureships in hygiene in Birmingham, including one at the Birmingham and Midland Institute Meanwhile he took the D P H in 1901, the B SC in public health of Birmingham University in 1905, and the M D in 1908 He had already entered the public-health service and he obtained varied experience while holding appointments with varied authorities, including those of the West Riding of Yorkshire, Sutton Coldfield, Warwickshire, and Handsworth

In 1908 he was appointed county M.O H for Hampshire, and during the next twenty-one years his work was centred on, but not confined to, Hampshire In his own area he set up sanatoria, an institution for mental defectives, and child-welfare centres, and over the years he also became a member of the medical board of the Lord Mayor Treloar's Hospital at Alton, of the faculty of medicine and board of studies in hygiene of the University of London, and of the Central Midwives' Board, a president of the Society of Medical Officers of Health, and editor of *Public Health* H C M W, who has helped us in these recollections, recalls that Lyster's dynamic personality and strong convictions often made him appear intolerant of other people's opinions, but adds that "many of his colleagues and assistants will look back with gratitude to the guidance and help that they received from him while he held office in the public health service"

In 1929 Dr Lyster retired, rather earlier than is usual, for he hoped to go into politics He stood as a Labour candidate in the parliamentary elections of 1929 and 1935, but he was unsuccessful. He had, however, been elected to the Bournemouth borough council and he later concentrated on local government, serving for many years as a valued and knowledgeable member of the council's health committee

EDWARD CECIL CLEMENTS

C B E , M.R C.S

Group-Captain Clements, formerly consultant in ophthalmology to the Royal Air Force, died on May 19 at the age of 81

He qualified from the Middlesex Hospital in 1901, and after a period of study under the elder Lang at Moorfields he went into private ophthalmic practice at Lincoln

As a Territorial officer he was called up as soon as war broke out in 1914, and it was during his service with the R A.M C that he observed that people in certain occupations, such as bank clerks and those using precision instruments, tended to lose their power to maintain binocular single vision and to become affected by eye-strain, which could not, as a rule, be compensated by correcting spectacles Appreciating that this was really an imbalance of binocular vision, or heterophoria, he instituted eye exercises and found that these improved or reduced the eye-strain After he was transferred to the Royal Flying Corps, and later to the Royal Air Force as an ophthalmologist, he noticed the same condition in pilots and realised its importance in judging distance when landing aircraft

He used the Maddox rod for diagnosis and Black's amblyoscope in treatment, and in 1918 he formed his school of heterophoria at the aviation candidates' medical board in London By this contribution to the growing study of orthoptics he undoubtedly reduced the wastage of pilots, both trained and undergoing training

In 1919 Clements was appointed to a permanent commission in the medical branch of the Royal Air Force as a squadron leader. A year later he was promoted to wing-commander and in 1928 to group captain. He continued to practise as an ophthalmic specialist throughout his service and he was appointed consultant in ophthalmology in 1931. A colleague who worked with Clements at Holly Hill, Hampstead, in the 20's recalls with awe his untidiness and with affection his kindness and generosity. He was created C.B.E. in 1934 and retired later in that year.

In recent years the approach to heterophoria has changed, but there can be no doubt as to the value of the work Clements did in the early days of aviation ophthalmology.

The photograph of Dr C. W. Buckley which we published last week was by Navana Vandyk, London.

Diary of the Week

JUNE 19 TO 25

Monday, 20th

POSTGRADUATE MEDICAL SCHOOL OF LONDON, Ducane Road, London, W.12
4 P.M. Dr Lewis Dexter (Boston): Cor Pulmonale.

Tuesday, 21st

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.1
5 P.M. Dr Kenneth Perry: Pulmonary Disease Associated with Metallic Oxide. (Ernestine Henry lecture.)
INSTITUTE OF DERMATOLOGY, St. John's Hospital, Lisle Street, W.C.2
5.30 P.M. Dr O. L. S. Scott: Hypostatic Ulcers.

Wednesday, 22nd

INSTITUTE OF DERMATOLOGY
5.30 P.M. Dr R. W. Riddell: Subcutaneous Mycotic Infections.

Thursday, 23rd

POSTGRADUATE MEDICAL SCHOOL OF LONDON
4 P.M. Dr J. C. Gilson: Rheumatism and Lung Disease.
INSTITUTE OF DERMATOLOGY
4.30 P.M. Dr Henry Haber: *Reticuloses.*

Friday, 24th

POSTGRADUATE MEDICAL SCHOOL OF LONDON
2 P.M. Mr John Bruce: Regional Enteritis.
4 P.M. Mr I. McG. Moffatt: Use of the Ophthalmoscope in Medicine. (Second of two lectures.)
ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1
8.15 P.M. *Obstetrics and Gynæcology.* Mr A. L. T. Easton, Dr Peter Andrews, Mr Stanley Way, Mr Anthony Charles: Carcinoma of the Vulva.

Saturday, 25th

RADCLIFFE INFIRMARY, Oxford
11.15 A.M. Dr Neville Oswald: Chronic Bronchitis.

Appointments

[illegible], H. C., M.R.C.S., D.P.M.: deputy medical superintendent, Rampton Hospital, Retford, Notts.

[illegible], R. S., M.B. Glasg., D.P.M.: whole-time asst. psychiatrist (S.H.M.O.), St. Nicholas Hospital, Gosforth, Newcastle upon Tyne.

[illegible], J. J., M.D. Camb., M.R.C.P., D.P.M.: asst. physician, department of psychological medicine, Guy's Hospital, London.

[illegible], L. L. W., M.B. Edin., F.R.C.S.E.: surgeon, Leith Hospital, Edinburgh.

[illegible], JOYCE C., M.B. Lond.: asst. geriatrician (S.H.M.O.), Northampton and Kettering H.M.C.s

[illegible], JACK, M.B. Glasg., D.O.M.S.: whole-time ophthalmologist, Royal Infirmary, Edinburgh.

[illegible], W. F. K., M.B. Belf., D.A.: part-time anæsthetist (S.H.M.O.), Banbridge and Dromore and South Down H.M.C.s

[illegible], CONSTANTIN, M.B. Lwow, D.A.: consultant anæsthetist, South Shields H.M.C.

[illegible], K. W., M.R.C.S., D.A.: asst. anæsthetist (S.H.M.O.), High Wycombe and district H.M.C.

[illegible], R. D., M.R.C.S., D.P.H.: deputy M.O.H., deputy principal school M.O., and deputy port M.O., Ipswich.

[illegible], P. M., M.B. Edin., F.R.C.S.E.: consultant surgeon, North West H.M.C., Northern Ireland Hospitals Authority.

[illegible], L. B., M.B. Lond., F.R.C.S.E.: whole-time asst. consultant plastic surgeon, Whiston Hospital, Alder Hey Children's Hospital, and the Royal Southern Hospital.

[illegible], FRANCIS, M.B. Lpool: asst. M.O. and deputy M.O., borough of Buckingham, Bletchley, Linslade and Newport Pagnell urban districts, and Buckingham, Newport Pagnell and Wing rural districts.

[illegible], A., M.B. Sheff., D.A.: whole-time anæsthetist, Moorgate General Hospital, Rotherham, Yorks.

[illegible], L. A., M.D. Aberd., M.R.C.P.: consultant physician (pediatrics) based on Glenburn Wing, Woodend Hospital, Aberdeen.

Amended notice.

Notes and News

MENTAL NURSING FILMED AGAIN

THOSE who saw *The Troubled Mind*[1] need not fear that *Light through the Clouds*—a film about nursing at The Retreat, York—will take them over the same ground; for though the two films have the same main theme (that of a young girl entering mental nursing) and both are skilfully photographed and well scripted, they are complementary rather than overlapping. In the first, emphasis is often on patients and their symptoms; in the second it is on methods of treatment. Neither perhaps gives a complete picture of mental nursing (if such a thing is possible) but together they come very close to doing it.

The Retreat is an exceptional hospital with one of the longest traditions in this country of humane care of the mentally ill; and *Light through the Clouds* conveys well the atmosphere of friendship and coöperation in which the work there is done. The rate of staffing is high—100 nurses to 270 patients—which may account for the unusually peaceful tempo at which things seemed to move. The early sequences show well that the nurse in a mental hospital learns all the techniques of sick nursing which would come her way in a general hospital—a fact not always appreciated by general nurses. Then follow examples of forms of treatment used specifically on mental patients—insulin coma, electroconvulsion therapy, and psychotherapy. The work of the physiotherapy and X-ray departments is also lightly sketched. Members of the nursing staff take the parts of patients, and certainly give no cause for alarm to young prospective nurses who may see the film. Some of the recreations of the nurses are shown, and the beauty of the setting of The Retreat, as well as the fine old house from which it has grown, are given their proper value. The commentary ends with a direct appeal to the young girls who might be interested—"the Janets and the Kathleens"—to consider mental nursing as a career.

The production and photography are by Mr C. Harold Wood, and the film has been made under the direction of Mr P. Thomas Oliver and Mr of Alan H. Pickard who also wrote the commentary.

A DOCTOR AND THE RAIL STRIKE

A DOCTOR in Birmingham has declined to see one of his patients, the wife of a railway striker, until the strike is over.[2] The patient had an appointment to see him privately, but after the strike began the doctor wrote to her husband:

> "I am afraid my principles prevent me from seeing patients who are on strike except in cases of emergency. . . . If you will 'phone for an appointment when the strike is over I will try to fix a convenient date."

The doctor is reported to have said that nothing in his refusal was detrimental to the patient. She was not ill now and the appointment was for a routine examination.

University of Oxford

Surgeon Rear Admiral James Hamilton has been appointed director of postgraduate medical studies for five years from Oct. 1.

On June 4 the degree of D.M. was conferred in absence on R. W. Gilliatt.

University of Cambridge

On May 28 the following degrees were conferred:

M.B.—William Atherton, A. E. L. le Thierry,* J. F. Walker.
* By proxy.

University of Durham

Dr Donald Court, reader in child health, has been appointed to the chair of child health in the Newcastle division of the university in succession to the late Sir James Spence.

Dr Court graduated in medicine at the University of Birmingham in 1930 and later became house-physician at Great Ormond Street Hospital and pædiatric registrar at Westminster Hospital. In 1935 he took the M.R.C.P. and the D.C.H. Before taking up his present appointment at Newcastle he held a Nuffield fellowship in child health. In 1947 he proceeded to his M.D. degree. He contributed the chapter on tuberculosis in *Garrod, Batten and Thursfield's Diseases of Children* and he has also published papers on the health of nurses. He is a joint author of recent publications on infantile mortality in Newcastle.

Royal Australasian College of Physicians

On May 11 the following were admitted to the honorary fellowship of the college Sir William Slim the governor general of Australia the Rt Hon Robert Menzies, the prime minister and Sir Russell Brain, F R C P

Royal Society of Medicine

At the 150th anniversary dinner of the society on June 7 the Duke of Edinburgh was made an honorary fellow an received a copy of the commemorative history of the societ written for the occasion by Dr Maurice Davidson, wh presented the volume The President, Sir William Gilliatt told the Duke that one of the privileges he would now enjo would be to borrow eight volumes at any one time from th R S.M library, which, Sir William said, might fairly be calle the National Medical Library of the Commonwealth, for, the society's 10,000 fellows, nearly 2000 lived oversea Like many similar institutions the R S M was much troubl by the rising cost of books, bindings, and paper, but the were good hopes, the President went on, that the generos of friends and the loyalty of fellows would enable them place their finances in an impregnable position Propos The Society, the Duke recalled the time when, in its earlier days, Robert Liston's 30 second leg amputation was as much the talk of the day as the 4 minute mile was now, Turning to the modern scene, he said he was sure that the whole essence of medicine lay in the personal relationship between doctor and patient, and that was why he was particularly glad to be present at an occasion where Sir William presided—though, he hastened to add, he had never actually been a patient of his In his response, Sir Francis Walshe, immediate past president of the society, spoke of the immense pride and pleasure of all the fellows in having the Duke with them, "in a double sense one of our number" The Guests, cordially proposed by Sir Arthur Porritt, drew sparkling replies from Lord Salisbury and Lord Adrian

Medical Association for the Prevention of War

Prof L S Penrose, F R S, will open a discussion on his book *The Objective Study of Crowd Behaviour* at 8 P M on Wednesday, June 22, at 45, Russell Square, London, W C 1 Dr Norman Glaister will be in the chair

Oxford Graduates' Medical Club

The summer dinner of this club will be held in Oriel College, Oxford, on Friday, July 1, at 7 P M, with Dr F G Hobson in the chair Members may bring medical men or women as guests Tickets (35*s*) may be had from Mr Ronald Macbeth, F R C S, department of otolaryngology, Radcliffe Infirmary, Oxford.

Hospitals' Symphony Orchestra

This orchestra is to give a concert at B.M.A House, Tavistock Square, London, W C 1 on Saturday, June 25, at 7 30 P M The programme will include Haydn's Trumpet Concerto, Brahms's Fourth Symphony, and works by Dvořák Sibelius and Berlioz Tickets (10*s*, 7*s* 6*d*, 5*s*, and 3*s* 6*d*) can be had from Mr Mitchell, the concert manager, St Thomas's House, S E 1

United States Supreme Court

On June 6 the court found that Dr John Peters, senior professor of medicine at Yale University, had been wrongfully dismissed as a "security risk" from his post as a government consultant in 1953 The court's majority opinion ordered the Civil Service Commission to strike from its records a finding by the old loyalty review board that there was a reasonable doubt as to Dr Peters's loyalty

Canadian Nuffield Fellows

Nuffield travelling fellowships in medicine have been awarded this year to the following Canadian doctors Dr H R Brodie, Dr W R N Lindsay, Dr D G Marshall, and Dr J A Palmer A travel grant has been awarded to Prof R L de C H Saunders, head of the department of anatomy, Dalhousie University, to study micro radiographic equipment in England

CORRIGENDA *A Ruler for Use in Electro encephalography and Electrocardiography* —In this article (June 4, p 1158) the third sentence in the third paragraph should read "Should lines other than those immediately adjacent to the vertical be used, the figures representing C P S and seconds are divided by 2 and 3 and multiplied by 2 and 3 respectively"

Pembury Hospital, Kent —In recording (June 4, p 1184) the dedication of a memorial window at this hospital, we gave the name of Mr J F Carter Braine incorrectly

THE INCIDENCE OF LEUKÆMIA IN ANKYLOSING SPONDYLITIS TREATED WITH X RAYS

A PRELIMINARY REPORT

W. M. COURT BROWN
M.B., B.Sc. St. And., D.M.R., F.F.R.

JOHN D. ABBATT
M.B. Edin., D.M.R.

MEMBERS OF THE EXTERNAL SCIENTIFIC STAFF, MEDICAL RESEARCH COUNCIL, DEPARTMENT OF MEDICINE, POSTGRADUATE MEDICAL SCHOOL OF LONDON

IN a discussion of a paper on the long-term evaluation of the treatment of ankylosing spondylitis with X rays (Robinson and Lampe 1948), Graham stated that 2 of his patients so treated had died of leukæmia. Since 1949 van Swaay (1954) has collected data on 7 people who had died from leukæmia and who also had X-ray treatment for ankylosing spondylitis.

In recent months an investigation has begun into the death-rate from leukæmia among people suffering from ankylosing spondylitis and treated with X rays. This investigation is being continued under the auspices of the Medical Research Council's working party on leukæmia research, and, while its final conclusions will not be reached for some considerable time, the findings to date are felt to be sufficiently important to warrant a preliminary report.

Provisional Findings

An attempt has been made to obtain information regarding the treatment of ankylosing spondylitis from all the radiotherapy centres of both England and Wales and of Scotland. The following information has been sought from each of fifty-eight different centres:

(1) The total number of patients treated with X rays for ankylosing spondylitis from 1940 to 1954 inclusively.
(2) The number of patients treated for the first time in each year of this fifteen-year period.
(3) The age and sex distribution.
(4) The number of patients given more than one course of X-ray treatment.
(5) The number of patients reporting back at intervals for medical examination.
(6) Records of any patient who had developed leukæmia, aplastic anæmia, or myelofibrosis.

Preliminary data have been collected on 9364 patients treated in thirty-seven Radiotherapy Centres, these including all except *four* of the *major centres*. The criterion for the inclusion of a patient in this series has been a diagnosis of ankylosing spondylitis at the time of his or her first X-ray treatment, even though subsequent to this the diagnosis may have been found to be in error.

It will be seen in the subsequent analyses of age and sex distribution, &c., that in each instance the number of patients analysed is *smaller than the total number* concerning which information has been obtained. The cause of this discrepancy is that many of the centres have not made a return of all the information that was requested. For this reason it has been found necessary in order to estimate the number of cases of leukæmia that might be expected to occur to make a number of assumptions in regard to the whole population based on analyses carried out on parts of the population. To avoid any tendency to underestimate the expected number of cases of leukæmia as these assumptions have had to be made, a number of safeguards have been adopted as will subsequently become clear.

Age-distribution

The age-distribution is known for 2697 patients of both sexes and is given in table I. The ages referred to are those of the patients when they were seen in a radiotherapy centre for the first time.

Sex-distribution

The sex distribution is known in 4297 patients of whom 3679 are males and 618 are females. The ratio of males to females is 5·95 : 1.

Patients kept under Observation

From the information supplied by seventeen radiotherapy centres concerning 3085 patients, an estimate has been made of the proportion of patients who are kept under observation after the conclusion of their X-ray treatment. Of the total of 3085 patients 1731 (56%) are periodically reporting back to the various centres for examination or are known to have died whilst the remaining 1354 patients (44%) have been lost sight of, either as a result of failure of the patients to report back to these centres or because periodical medical examinations have been dispensed with on account of the continuing good health of the patients.

TABLE I—AGE DISTRIBUTION OF 2697 PATIENTS

—	0–14	15–24	25–34	35–44	45–54	55–64	65–74	75–
Absolute numbers	4	415	1000	733	363	160	25	1
% of total	0·15	15·39	37·08	27·16	13·46	5·93	0·92	0·04

More than One Course of X-ray Treatment

In a proportion of patients it is found necessary to give more than one course of X-ray treatment to keep the disease under control. In a series of 2361 patients 797 (33·8%) were given more than one treatment course.

Patients who got Leukæmia

Records have been obtained of 25 patients who have developed leukæmia (table II) and this total of cases is likely to be incomplete as many of the 9364 patients—perhaps as many as 44%—have not been kept under observation. But it does not necessarily follow that the number of deaths is as incomplete as was the follow-up of the patients, because the fact of death may have been more readily reported back to the radiotherapy centre concerned. On the other hand it must be borne in mind that a number of patients are likely to fail to report back to the centres because they have died, but the centres themselves, unaware of the cause for non-attendance, may record them as being "lost sight of."

4 patients are included in whom leukæmia and ankylosing spondylitis were considered to be co-existent when the patients were given X-ray treatment for the first time.

TABLE II—RECORDED CASES OF LEUKÆMIA

Total	Age-distribution (years)		No. with apparent co-existence of leukæmia and spondylitis	No. having one treatment course only	No. having more than one treatment course	Latent period† (months)	
	Range	Mean				Range	Mean
25 (21)	17–65	36	4 (4)	6 (5)	15 (12)	[illegible]–161	74

Types of leukæmia

Clinical		Cytological			
Acute	Chronic	Lymphatic	Myeloid	Monocytic	Unspecified
19	6	2	11	8	4

Figures in parentheses refer to numbers of patients notified to the Registrar-General as dying from leukæmia.

† Time interval between start of first course of treatment and the clinical recognition of leukæmia, in those patients who did not apparently have co-existent leukæmia at the time of first treatment of their ankylosing spondylitis.

Expected and Observed Deaths from Leukæmia

The death-rates from leukæmia in England and Wales have increased steadily since 1940 (table III) There has been a similar but less consistent upward trend in the Scottish death rates

In this preliminary report an approximate estimate of the number of deaths from leukæmia which might have been expected to occur among all the 9364 patients has been made in the following way

TABLE III—DEATH RATES FROM LEUKÆMIA FOR ENGLAND AND WALES AND FOR SCOTLAND, 1940–1953 (REGISTRAR GENERAL)

Year	Deaths per million living persons			
	England and Wales			Scotland
	Male	Female	Both sexes	Both sexes
1940	30	23	26	38
1941	29	22	25	28
1942	34	24	28	27
1943	38	25	30	32
1944	38	26	31	32
1945	40	29	34	32
1946	41	30	35	34
1947	38	32	35	32
1948	40	31	35	30
1949	44	35	40	39
1950	47	37	42	39
1951	47	41	44	43
1952	52	41	46	41
1953	53	44	48	38

The numbers of patients known to have been aged 0–14, 15–24 25–34, &c , shown in table I have been multiplied by the age specific death-rates for men in England and Wales in 1953 The rates for men have been used because the greater proportion of the treated patients whose sex was known were men (86%) and because the death-rate from leukæmia was, in general, slightly higher in men than in women The rates for 1953 were used because the death-rate from leukæmia has been rising throughout the period studied (table III), and by using the latest (and highest) rates available the expected number of deaths will be overestimated rather than underestimated

If it is assumed that the age-distribution of the whole 9364 patients is the same as that of the 2697 patients analysed in table I, then the total number of deaths, expected to have occurred in one year can be obtained by multiplying the sum of the expected numbers for each group by the factor 3 472 (9364/2697)

At this point a further consideration must be taken into account The patients were treated up to fifteen years ago and, therefore, have been exposed to the risk of dying for a number of years During these years the patients have also aged and, depending upon their age-groups, have been exposed to a greater or lesser risk of dying as they aged In a series of 6187 patients from twenty-six radiotherapy centres, only 12% of the patients entered the series during the first quinquennium and as many as 49 3% entered it during the last quinquennium If it is assumed that all the patients in the series have, on the average, been observed for ten years, the expected number of leukæmia deaths for the whole period will not be underestimated and will be obtained by multiplying by a further factor of ten Also, on the average, all the patients will have aged five years during their period of observation, so that instead of multiplying the numbers of patients in the age-groups 0–14, 15–24, 25–34, &c., by the mortality-rates for these groups themselves they must be multiplied by the mortality-rates for the age-groups five years in advance, i e , 5–19, 20–29, 30–39, &c

The total number of leukæmia deaths expected for the whole period is, therefore, the sum of the expected numbers in the individual age-groups (0 1125) multiplied by 3 472 × 10—that is, 3 9

Only those deaths observed in the series and certified as being due to leukæmia can be compared with the estimate of the expected number of deaths since the estimate of the expected number of deaths is based on the causes of death certified to the Registrar General 21 of the observed cases of leukæmia were certified as dying from leukæmia If it is assumed that no other cases of leukæmia have occurred in the untraced sections of this population then the ratio of observed deaths to expected deaths is 21 3 9 or 5 4 1 If, however, it is assumed that the same proportion of leukæmia deaths has occurred in the untraced section of the irradiated population as in the traced section, then the ratio of observed to expected deaths may well be as high as 37 3 9 or 9 5 1

12 of the patients certified as dying from leukæmia were given more than one course of X ray treatment From the information provided by thirteen centres about 2361 patients, 33 8% were found to have had more than one treatment course If it is assumed that this proportion is the same in the whole population of 9364 patients, the ratio of observed deaths to expected deaths is 12 1 32 or 9 1 1 It is not possible to make an estimate of the proportion of those patients given more than one treatment course who are untraced, and consequently an estimate cannot be made of the total number of cases of leukæmia that may have occurred in that group *

Discussion

The object of this preliminary report is to call attention to the high number of deaths from leukæmia amongst a series of *patients suffering from ankylosing spondylitis* and treated with X rays Other causes of death, such as aplastic anæmia, will be dealt with in a later communication

In this report a number of assumptions have been made, especially in regard to the age distribution Thus, it is possible that the age distribution of ankylosing spondylitis differs in the two sexes and it is likely that the mean age of these patients will have increased somewhat in the latter part of the fifteen year period when fewer patients were being referred for treatment from the Armed Services It is, however, probable that any tendency that these assumptions may have had to underestimate the expected number of deaths is more than offset by the use of the highest recorded death-rate from leukæmia in this calculation, by the absence of any correction for sex-distribution, and by the assumption of a mean period of observation of ten years

4 patients have died in whom leukæmia and ankylosing spondylitis were considered to be co existent before the institution of X ray treatment Also 1 patient died of leukæmia two months after the start of X ray treatment, and his leukæmic state may have been present when treatment was begun, though unrecognised Bearing in mind that the estimated number of leukæmia deaths—i e , 3 9—is likely to be artificially high through the adoption of a number of safeguards, and that it also relates to a ten-year period of observation, it is not possible to exclude some association between the two diseases No attempt has been made to review the diagnoses in any of those cases in which both leukæmia and ankylosing spondylitis were said to be co existent If both diagnoses are correct in each of the 4 cases, there is a possibility that persons suffering from ankylosing spondylitis are more liable to develop leukæmia than the general population of England and Wales of the same age distribution and sex distribution On the other hand, it is possible that in some cases errors in diagnosis have been made, and that the pain and disability suffered by the patients were solely due to the leukæmic processes If this were so the argument in favour of an association between the two diseases would be less strong Bearing

---

* If it is assumed that the same proportion of the patients receiving more than one course of X ray treatment is untraced as is the case for the whole population, then the ratio of observed to expected cases of leukæmia would be as high as 21 1 32 or 15 9 1 It is, however, probable that patients receiving multiple courses of treatment are more likely to be kept under observation than those given only a single course of treatment

in mind these possibilities it is now pertinent to examine the evidence suggesting that X irradiation may have been a major cause of the unexpectedly high numbers of patients found to have leukæmia.

15 patients who had more than one course of X-ray treatment developed leukæmia, while 6 patients had leukæmia after only one course of treatment. It has already been shown that 33·8% of a series of 2381 patients had more than one treatment course. Assuming that the same proportion of the total population of 9364 patients had more than one course, then 1 patient in every 211 patients treated in this way developed leukæmia in contrast to 1 patient in every 1033 patients who had only one course of treatment. If these groups of patients are comparable with regard to sex, age, and duration of observation, the difference between them in the incidence of leukæmia is appreciable (χ^2 = [illegible], n = 1, P < 0·001). This finding that the incidence is higher among those treated more than once is only to be expected if X irradiation is an important factor in determining the occurrence of leukæmia, for it is reasonable to suppose that the greater the number of treatment courses the greater the risk of leukæmia.

Before the X-ray treatment can be finally accepted as a major cause two further considerations must be examined. In the first place it is not possible to be certain that some of the patients who developed leukæmia after a second course of treatment were not in fact given this second course on account of pain and disability caused by the leukæmic process, this not being recognised at the time. If this were the case then the significance of the difference between the two groups would be diminished and might even disappear. While in the cases that have been reported there is no evidence that this has occurred, it is a theoretical possibility that must be considered. In the second place it is fair to assume that those patients requiring more than one treatment course were suffering from a more severe form of ankylosing spondylitis than those requiring only one course of treatment. There is no evidence, either clinical or statistical, to refute an argument that the severer form of the disease is not itself associated with a greater predisposition towards the development of leukæmia than the less severe form.

It is clear that on the evidence presented so far no final conclusions can be reached on the part played by X-ray therapy in the production of the increased numbers of cases of leukæmia in this series of cases of ankylosing spondylitis. It is, therefore, relevant at this point to discuss the reported examples of the development of leukæmia following the exposure of persons to ionising radiations, apart from the purpose of treating malignant disease.

It is now recognised that an increase has occurred in the death-rates from leukæmia in both Nagasaki and Hiroshima, attributable to the atomic explosions occurring over those cities in 1945 (Folley et al. 1952, Lange et al. 1954, Moloney and Kastenbaum 1955). Merklen et al. (1925) reported the development of chronic myeloid leukæmia in a woman seven years after X-ray treatment for uterine fibromata, and Gerbis (1943) and Lynch (1951) reported acute myeloid leukæmia following the use of X rays in the treatment of non-malignant skin lesions. More recently Simpson et al. (1955) have claimed a statistically significant increase in the incidence of leukæmia and of carcinoma of the thyroid in a series of children given X-ray treatment in infancy because of suspected enlargement of the thymus gland. There is evidence also that occupational exposure to ionising radiations may be associated with an abnormally high death-rate from leukæmia. In particular, a number of reports establish a good case for such an increased death-rate amongst physicians practising radiology (Ulrich 1946, March 1950, Peller and Pick 1952).

The evidence from the literature suggests that exposure to ionising radiations can be leukæmogenic in man. Leukæmia has occurred in association with an acute whole-body exposure following the explosion of a nuclear device, with various forms of radiotherapy, and with chronic occupational exposure. On this basis and in spite of the difficulties in the interpretation of the present findings it is perfectly reasonable to conclude that some, perhaps the great majority, of the cases of leukæmia found in this series have occurred as a result of X-ray treatment. The fact that sufferers from ankylosing spondylitis may be unusually susceptible to the development of leukæmia has also been stressed, but only further research can evaluate the relative parts played by the possible susceptibility of these patients to leukæmia and the X-ray treatment.

In spite of these findings it would be wrong to withhold X-ray treatment from those suffering from ankylosing spondylitis. It is common knowledge that the life-expectancy of many of these patients is reduced by their disability, and most authorities agree that radiotherapy has in many instances a beneficial effect. What is certain, however, is that no one should be treated with X rays unless the diagnosis is clearly established, and that a second course of X-ray treatment should not be given unless absolutely necessary.

Summary

(1) An inquiry is being made into the death-rate from leukæmia amongst patients suffering from ankylosing spondylitis and treated with X rays.

(2) A series of 9364 patients treated from 1940 to 1954 inclusively has been analysed and the expected number of deaths from leukæmia in this series has been calculated on the basis of the male age-specific death-rates from leukæmia in England and Wales for 1953.

(3) The observed deaths from leukæmia have been found to be at least five times, and possibly as many as ten times, the expected number of such deaths, and amongst those patients given more than one course of X-ray treatment the observed deaths are probably at least nine times those expected to occur.

(4) Evidence has been put forward which suggests that patients with ankylosing spondylitis may be unusually susceptible to the development of leukæmia. But also it is likely that the incidence of leukæmia is appreciably raised amongst those patients given more than one course of X-ray treatment.

(5) Reviewing the above findings in the light of a number of reports in the medical literature it is concluded that some, if not the majority, of the observed cases of leukæmia may be attributable to X irradiation.

(6) Further investigation is necessary to confirm these findings.

We are grateful to all those radiotherapists and other colleagues who have kindly supplied us with data. A more detailed acknowledgment will be made in a later communication.

We would like to acknowledge the help given to us in the preparation of this paper by Prof. L. J. Witts, Prof. B. W. Windeyer (with whose coöperation the early stages of the investigation were made), Prof. A. Bradford Hill, and Dr. W. R. S. Doll.

THE NATURAL HISTORY OF PERIPHERAL TUBERCULOUS LYMPHADENITIS ASSOCIATED WITH A VISIBLE PRIMARY FOCUS

DEPARTMENT OF CHILD HEALTH, ROYAL VICTORIA INFIRMARY, NEWCASTLE UPON TYNE

KNOWLEDGE of the relation of the time and site of the primary tuberculous infection to its manifestation and observation of the ultimate result are particularly important in the study of peripheral tuberculous lymphadenitis, which is still often said to be "most often a *manifestation of generalised tuberculous infection*" (American Trudeau Society 1954)

Since 1947 we have been studying primary tuberculosis of skin and mucosa Primary infection on these sites has proved to be much more common than at first seemed possible, and 28 cases have been described (Miller 1953) Since then further cases have been seen and, if we include those with visible primary lesions of tonsils and mouth, we have 40 children with visible primary tuberculosis who have been under observation for a minimum of two years In this group the site, and, within narrow limits, the time of primary infection are known, and we have observed the behaviour of the regional glands in neck, groins, and axillæ Though the cases were first seen in differing stages of evolution, we think they form the basis of a study of the natural history of peripheral tuberculous lymphadenitis

Therefore we report here the changes in the glands in these 40 children , but before doing so we must explain our diagnosis of primary tuberculosis and distinguish between clinical and experimental work—i e , between probability and proof In clinical work we do not impose our own conditions on the material studied and we deal with reasonable probabilities Thus if we are to prove that any manifestation of tuberculosis is part of a primary complex—i e , primary focus and regional glands—we should observe the tuberculin conversion of the patient as well as demonstrate a primary tuberculous focus and its associated regional glands This proof is usually absent apart from occasional, almost accidental, observations But if we can show by a combination of clinical, histological, and bacteriological techniques that a tuberculous focus exists, and that the regional glands are the site of caseous change, we can use the pathological studies of Ghon and Terplan to support the probability that we are witnessing a primary infection in the person concerned (Terplan 1940)

It is strange that there is no agreement on the pathogenesis of tuberculous lymphadenitis, and that we cannot find an accurate account of the natural history of this condition The main reason seems to be that no worker has described a series of cases in which the time of the primary infection, whether recent or remote, was known accurately, and most accounts do not discuss the presence or absence of manifestations of tuberculosis elsewhere in the body

The best published report that we have found is that of Thompson (1940), also working on Tyneside, who reviewed 324 cases of tuberculosis of peripheral lymph-nodes His purpose was more to describe the pathogenesis than the natural history, but he did conclude

> "That whatever method [of treatment] was employed the disease usually followed a prolonged and relapsing course, tending ultimately to local healing with a greater or lesser degree of scar formation accompanied by contraction with fibrosis or calcification of the affected lymph glands "

He said also

> " There is some doubt whether gross tuberculosis occurs in lymph nodes infected other than during the primary phase, " and " it follows that the group of lymph nodes initially involved should indicate the portal of entry of the infection "

We feel that by observing a group with a known pathogenesis and time of infection we have the opportunity to make an accurate record of the natural history in a small well defined group of cases

Clinical Cases

The distribution of the primary foci and the regional glands is shown in figs 1 and 2 All the children were tuberculin-positive, the tuberculous nature of the process was proved, and all the children were observed for at least two years after infection

Tuberculous lymphadenitis is still common in the North east of England, and 224 cases (2%) were seen in 11,400 admissions to the children's department of the Royal Victoria Infirmary in the seven years 1947–53

Descriptions of representative lesions in skin and mucosæ have already been given In table I nos 1–23 and 25–28 refer to the same cases the original case 24 has been excluded because he was an adult, and another has been substituted (Miller 1953)

The behaviour of the glands can perhaps best be described by answering five questions How do they present ? How many soften to form abscesses, and how long do they take to do so ? How many calcify and in how long ? What are the complications of the visible primary complex ? How long do the glands take to heal after spontaneous rupture has occurred, and what is the period of morbidity ?

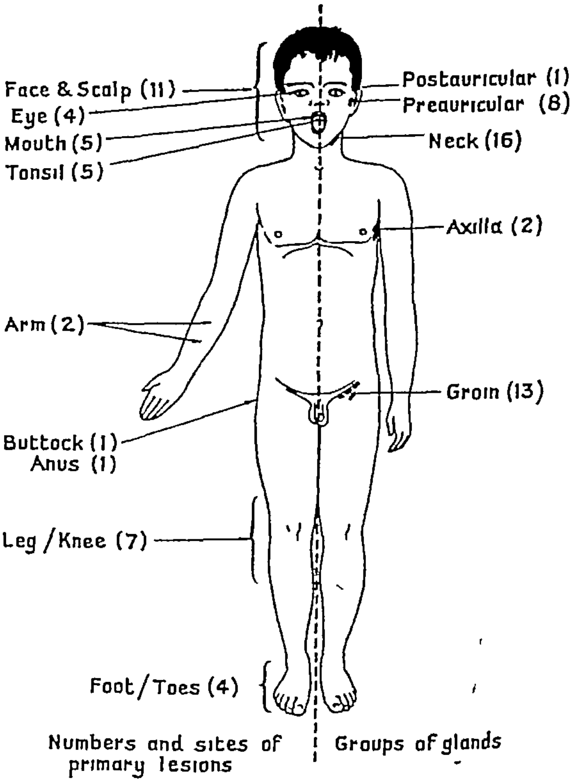

Fig 1—Distribution of sites of primary infection and groups of glands affected

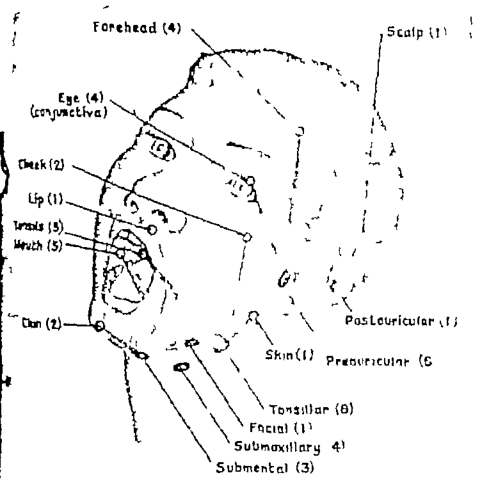

Fig. 1—Relationship between site of primary infection and regional glands first infected in head and neck.
○ = site of primary infection; **O** = first regional gland

How do the glands present?

Table I shows that 23 cases came to hospital after the accidental discovery by the mother or the child of a painless gland swelling; in another 4 the onset was much more acute with rapid swelling, pyrexia and some pain simulating an acute pyococcal adenitis; of these in case 20 the onset followed a cut by a piece of broken glass and was so rapid with such acute swelling that a double infection was almost certain.

In 7 cases a painless primary lesion was the first complaint, whereas in another 5 the primary lesion and the glands were noted simultaneously; the remaining child was admitted to hospital with miliary tuberculosis and the primary focus then discovered.

The absence of pain often seemed to delay consultation with the doctor; no less than 23 of the glands were already soft when first seen, and in 10 of these the abscesses had already ruptured. In the remaining 17 cases the glands were still firm.

In 8 of the 12 cases where the primary lesion alone or simultaneously with the gland had been the first complaint, an abscess had already formed when the child was first seen in hospital.

Less than half the children (15) had any systemic illness at the time of the appearance of the glands; pyrexia varied from a slightly raised temperature lasting a few days to a definite illness—the "fever of onset"—lasting three weeks (Wallgren 1948).

TABLE I—SYNOPSIS OF DATA OF 40 CASES OF PERIPHERAL TUBERCULOUS LYMPHADENITIS

Case no.	Site of primary lesion	Primary gland group	State of gland when first seen	Time from infection to softening	Course and surgical management	Pyrexia at onset	First symptom
1	Skin	Femoral	Firm	4 weeks	Aspirated	–	Swelling in groin
2	Cheek	Preauricular	Firm	5 mos.	Ruptured	–	Spot on face and swelling in front of ear
3	Knee	Inguinal	Soft	Not known	Ruptured	+	Acute inguinal adenitis
4	Heel	Inguinal	Ruptured	8 weeks	Incised	–	Inguinal adenitis and lack of healing
5	Knee	Inguinal	Ruptured	Not recorded	Incised	–	Inguinal swelling
6	Foot	Inguinal	Soft	4 mos	Incised	+ (Injury)	Lack of healing after accident
7	Arm	Axillary	Soft	2 yr	Excised	–	Axillary adenitis
8	Toe	Inguinal	Ruptured	3 mos	Incised		Swelling in groin
9	Knee	Inguinal	Ruptured	8 mos	Excised	–	Red area on knee
10	Calf	Inguinal	Ruptured	3 mo	Excised	+	Acute inguinal adenitis
11	Knee	Inguinal	Soft	4–5 mos	Excised	–	Scab did not heal
12	Chin	Submental	Soft	3 mos	Aspirated	–	Swelling under chin
13	Anus	Upper inguinal (bilateral)	Ruptured	2 weeks	Aspirated	+	Swelling in groin
14	Chin	Submental	Ruptured	3 mos	Ruptured	–	Lesion on chin, submental abscess
15	Cheek	Tonsillar	Firm	11 weeks	Aspirated ruptured	–	Spot on face, tonsillar gland swelling
16	Forehead	Preauricular	Ruptured	1 month	Incised	Erythema nodosum	Wound did not heal
17	Forehead	Preauricular	Ruptured	3 weeks	Incised	–	Scab on forehead and abscess in front of ear
18	Scalp	Postauricular	Soft	5 mos	Ruptured	+ (Injury)	Postauricular abscess
19	Calf	Inguinal	Soft	Not known	Incised	Erythema nodosum	Ill on admission after measles
20	Foot	Inguinal	Firm	6 weeks	Excised	+	Septic foot and acute adenitis
21	Eye	Preauricular	Soft	8 weeks	Ruptured	–	Sore eye
22	Eye	Tonsillar	Firm	3 mos	Incised	Erythema nodosum	Swelling of tonsillar gland
23	Eye	Preauricular	Soft	8 mos	Ruptured	–	Chronic conjunctivitis
24	Buttock	Lower inguinal (bilateral)	Ruptured	4 weeks	Incised	–	Abscess in groin
25	Eye	Preauricular	Firm	6 weeks	Incised	–	Small swelling in front of ear
26	Mouth	Facial (supramandibular)	Firm	1[illegible] mos	Incised	–	Ulcer in mouth
27	Mouth	Submaxillary	Firm	6 weeks	Aspirated	+	Submaxillary swelling
28	Mouth	Submaxillary	Soft	10 weeks	Aspirated incised	–	Submaxillary swelling
29	Skin above lip	Submental	Firm	[illegible] mos	Ruptured	+	Swelling in neck
30	Skin below ear	Tonsillar	Soft	4 weeks	Incised	–	Swelling in neck
31	Forehead	Preauricular	Soft	32 mos.	Aspirated incised	+	Swelling of cut, swelling in front of ear
32	Forearm	Axillary	Soft	3 mos	Aspirated incised	–	Swelling in axilla
33	Forehead	Preauricular	Firm	11 weeks	Incised	–	Lump under jaw
34	Mouth	Submaxillary	Firm		Excised	–	Lump under jaw
35	Mouth	Submaxillary	Firm		Excised	–	Swollen jaw
36	Tonsil	Tonsillar	Firm		Excised	+	Lump in neck, pyrexia
37	Tonsil	Tonsillar	Firm	1 month	Incised	Erythema nodosum	Lump in neck
38	Tonsil	Tonsillar	Firm		Excised		Swollen gland
39	Tonsil	Tonsillar	Firm		Excised		Swollen glands
40	Tonsil	Tonsillar	Firm		Excised	–	Swollen gland

TABLE II—TIME FROM INFECTION TO ABSCESS FORMATION

Time (mos)	< 3	3–6	9	12	24	32	Unknown
No of cases	14	11	3	1	1	1	3

4 of these had erythema nodosum, and 4 others the acute reaction and severe lymphadenitis with pain simulating pyococcal infection (Miller 1952) In 23 there was either no alteration of health or it was so slight as to escape notice In 2 cases the tuberculosis was a complication of severe trauma received in a road accident The source of infection and the relationship to trauma have already been considered (Miller 1953)

29 of the children had radiographs taken of the chest and 11 had radiographs of the abdomen when they were first seen Calcification was not visible in any In case 14 a second active primary complex was seen in the lung, and case 19 had miliary tuberculosis These were the only cases with clinical evidence of tuberculosis other than the primary complex

How many glands soften and how long do they take to do so?

We have already stated that 23 of the glands had softened to form abscesses when they were first seen and the remaining 17 were firm 6 of the firm glands were removed by local dissection before an abscess formed In the remaining 11 abscesses formed, making a total of 34 abscesses in the 40 cases No less than 25 had softened within six months and 29 within a year (table II)

Of the 12 glands which were firm when first seen and went on to soften 3 were treated with streptomycin while still firm They diminished in size as the periadenitis resolved, but all ultimately softened—i e , all the glands not removed when firm eventually formed abscesses

In how many cases and after how long did radiographic calcification take place?

We were concerned to discover how many of our cases developed calcium in the glands, and when it appeared If all or most of these proved cases did so, the presence of calcium can be used in other series to support a diagnosis of tuberculosis and to estimate how long the infection has been present

In 28 of the 40 children visible calcium developed at the site of the regional lymphatic glands Of the 12 others 4 had the glands excised (3 before and 1 after softening had taken place), 1 died, and 2 have been infected just over two years Possibly we may yet detect calcium in these 2 and in some of those whose glands were excised (3 of the patients in whom the presenting glands were firm when excised have developed calcium in neighbouring glands), but we do not know why the remaining 5 do not show calcification—possibly all the caseous material was discharged

We were not able to radiograph each child annually, and we cannot set out a complete table of the time of the appearance of calcium from infection, but of 15 cases examined a year after infection only 4 had visible calcium, whereas 18 other cases appeared by the end of the third year, making a total of 22 from 35 examined, In 24 of the 28 cases calcium was present within five years of infection (table III)

Calcification is therefore to be expected in the regional glands of a primary lesion on skin or mucosa, and in our series was seen within our period of observation in 28 from 39 possible cases

36 of the children had radiographs of the chest and abdomen two or more years after infection Case 14 proved to have calcified hilar glands (this was the child who was known to have an active primary lesion in the chest at the same time as the primary lesion on the skin), the remaining chest films were clear Calcification was shown in three abdominal films Two of these were calcification in the deep iliac glands of 2 patients who had primary lesions on the leg and calcified inguinal glands The third was an unexpected finding in 1 of the children with a primary tonsillar infection and calcified cervical glands Of the remaining 4 children 1 died, and 3, though seen for two or more years after infection, did not attend for subsequent radiography

TABLE III—RELATIONSHIP OF CALCIFICATION TO TIME OF INFECTION

Radiographic examination of regional glands	Calcification	Years after infection								Total
		0	1	2	3	4	5	6	7	
First	Present		4	1	6	1	0	1	1	14
	Absent	14	5	4	1	0	1	0	1	
Subsequent	Present for first time		0	7	4	1	2			14
	Still absent		6	7	6	2	2	1	2	
	Total calcified		4	12	22	24	26	27	28	28

What are the complications?

1 child developed miliary tuberculosis and fatal tuberculous meningitis 3 of the 40 children had erythema nodosum, 3 others phlyctenular conjunctivitis, and 1 both No case of bone or joint tuberculosis has yet occurred in these 40 children

The commonest complication of the primary complex was abscess formation in the group of glands draining from the primary gland Secondary abscesses did not occur in the 6 children whose primary glands were removed by dissection before softening, but in the 33 others (excluding the death) there were 17 who had subsequent abscesses in glands further down the lymphatic chain These usually appeared within a year of the first abscess, but 1 appeared as long as seven years afterwards In 1 child, whose glands had not broken

TABLE IV—TIMES BETWEEN SOFTENING OF SUBSEQUENT ABSCESSES

Case no	First abscess	Interval	Second abscess	Interval	Third abscess	Interval	Fourth abscess	Interval	Fifth abscess
2	Preauricular	5 mos	Tonsillar						
5	Inguinal	6 mos	Deep iliac						
8	Inguinal	3 mos	Inguinal	30 mos	Deep iliac				
14	Submental	3 mos	Upper deep cervical						
16	Preauricular	2 mos	Tonsillar	6 mos	Post-sternomastoid				
17	Preauricular	11 mos	Tonsillar	1 month	Post-sternomastoid	17 mos	Upper deep cervical	3 mos	Preauricular
18	Postauricular	Local recurrence at intervals of 4 mos			10 mos, and 7 mos				
21	Preauricular	4 mos	Tonsillar						
22	Tonsillar	15 mos	Submaxillary						
25	Preauricular	5 mos	Tonsillar	6 mos	Post-sternomastoid				
26	Facial	6 mos	Submaxillary						
27	Submaxillary	13 mos	Submaxillary						
28	Submaxillary	3 mos	Submaxillary	3 yr	Tonsillar				
29	Submental	6 yr	Submaxillary						
31*	Preauricular		Tonsillar		Upper deep cervical				
33	Preauricular	3 mos	Tonsillar	15 mos	Post-sternomastoid				
37	Tonsillar	4 mos	Upper deep cervical						

* All softened simultaneously after measles 3 years after primary infection

TABLE V—TIME OF HEALING OF ABSCESSES

Abscesses	No of cases	Healed by first intention	Months from first operation (or rupture if no operation)				
			< 3	3–6	12	>12	Not recorded
Ruptured spontaneously							
Excised	2	1		1			
Incised or aspirated	8	1	4	[illegible]	1		
No operation	7		1	1		3	2
Softened but did not rupture							
Excised	5	4			1		
Incised or aspirated	12	1	5	3	1		2
Excised while firm	6	6					
Total	40	13	10	[illegible]	3	3	4

down for three years after primary infection on the forehead, the preauricular tonsillar and post sternomastoid glands all softened simultaneously after measles. of these 17 children had not only a second abscess but also a third further down the path of lymphatic drainage thus in case 33 the preauricular gland was first involved the tonsillar second and the posterior sternomastoid third. Case 17 had 5 abscesses (table IV)

How long does healing take after spontaneous rupture or operation, and what is the total period of morbidity?

All the cases eventually healed, but Thompson's opinion, quoted above of the natural course of tuberculous lymphadenitis with abscess formation seems to be valid still for the patients we see in hospital The glands which underwent spontaneous rupture, or were incised, were often slow to heal or broke down after initial healing So far as it affected the natural history, the management is described here

Of the 17 glands firm when seen 6 were excised and healed by first intention Of the 34 which softened 17 ruptured spontaneously (3 of which were firm when first seen and 4 soft), 2 were excised 8 incised or aspirated, and 7 allowed to heal without intervention The times taken for healing are shown in table V

TABLE VI—MORBIDITY

Duration (from infection) of inpatient and outpatient attendance at hospital

	Months				Years					
Time	0–6	6–12	12–18	18–24	2–3	3–4	4–5	5–6	6–7	7–8
Numbers	1	12	6	4	8	3	4		1	1

Of the remainder of the soft glands (8 firm and 9 soft when first seen) 5 were excised and 12 aspirated or incised. The duration of the sinus is shown in table V

Table V refers to the time taken for the first gland abscess to heal, but many children had more than one abscess, or their general condition made a long period of hospital care or outpatient supervision necessary The total duration of this morbidity is shown in table VI The time has been taken from infection to discharge from hospital, sanatorium or outpatient supervision and does not include visits made at our request 2 children are still attending—four years and two years after infection In some cases there was a gap of a year or two between hospital attendances. Moreover it is always possible that further complications may arise

Discussion

We have shown that the regional glands in 40 cases of primary tuberculosis with visible primary foci showed a striking tendency to soften Indeed all did so except those removed by dissection while firm In a few cases softening did not take place until more than a year after infection and after calcium had appeared The objection might be raised that because 23 of the glands had softened when first seen, the series was highly selected but there were 11 firm when first seen which were not excised and all these softened also

All the children except 3 came from "artisan or labouring" families. We do not know whether tuberculous adenitis in children of other social groups has the same tendency to soften but we do know that our experience in these 40 cases is in accord with the natural history of cases of tuberculous adenitis seen in our department, whether or not associated with a visible primary focus But the question always remains how often and in what circumstances does primary tuberculous peripheral lymphadenitis occur without softening but with the deposition of calcium? We have not yet a precise answer but we think it must be uncommon, probably occurring mainly in the upper social groups. Another piece of indirect evidence is the extreme rarity with which we find calcium in the neck in routine radiography without an overlying scar or sign of abscess We therefore feel that primary tuberculous peripheral lymphadenitis, as seen in the north east of England, is likely to proceed in most cases to abscess formation

If an abscess does form in the primary gland the possibility of an abscess in the next group of glands is high—17 in 33 (half our children) This prolongs the period of morbidity and makes a good cosmetic result more difficult to obtain

We have shown that calcification is visible in most of our cases and commonly appears in the second and third years after infection but possibly later Its appearance indicates the cause of a lymphadenitis of doubtful origin and allows an estimate of the time of infection where this is unknown Furthermore the presence of calcium can be used as a method of investigating the natural history of tuberculous lymphadenitis and we hope to continue this study by a review of some 350 cases seen in our department in seven years

Summary

We have studied the behaviour of the regional glands in 40 cases of primary tuberculosis of the skin and mucosa

In all the cases other than those 6 in which firm glands were removed by dissection the glands softened and abscesses formed In most cases this took place within six months of infection.

In 28 of 39 cases calcium was seen in the glands—none in the first year but in more than half the cases in two or three years In England the presence of calcium can therefore be used as diagnostic evidence and to estimate the time since primary infection

We wish to thank our colleagues in the department of child health and other departments of the hospital who referred cases of visible primary tuberculosis, and the members of the departments of bacteriology pathology, and radiology for their help

That was the trouble with courage perhaps: too many men had it The men in brown and the men in green the men in the Marauders and the men in the Junkers the men fighting each other with stones and clubs and axes and spears and swords and catapults and bowie knives and flint locks and Gatling guns and Bren guns and detonation bombs and fragmentation bombs and delayed fuse bombs and butterfly bombs and V 1 and V 2 and V 1000 They all had courage—did have it—would have it It was a terrible thing to admit perhaps but after enough years of killing and not being killed you got a little tired of courage There was so damned much courage in the world and so damned little wisdom '—J R ULLMAN *The White Tower* London 1954; p 375

USE OF ISOTOPE-LABELLED RED CELLS TO DEMONSTRATE INCOMPATIBILITY IN VIVO

P L MOLLISON

MARIE CUTBUSH
B Sc Melb

From the Medical Research Council's Blood Transfusion Research Unit, Postgraduate Medical School of London

In selecting blood for transfusion it may be difficult to decide whether a reaction occurring in vitro implies that red cells will be destroyed in vivo For example, cross matching may reveal the presence of a specific antibody strongly active at low temperatures but doubtfully active at 37°C , in other cases all blood samples may react weakly with the patient's serum at 37°C, suggesting the presence of a non specific antibody In such cases there is a real need for a biological test to supplement tests in vitro

The earliest biological test introduced into transfusion work consisted simply in injecting a small volume of the donor's blood and looking for a clinical reaction A later refinement consisted in injecting the donor's blood in amounts of about 50 ml and looking for increases in bilirubin or for the presence of free hæmoglobin in the recipient's plasma (Wiener et al 1942) However, this test is not very sensitive (see Mollison 1951) Compatibility can be reliably assessed only by measurement of the survival of the injected cells

Until recently the survival of transfused cells could be measured only by differential agglutination This method is practicable only when donor and recipient belong to different ABO or MN groups and when an injection of at least 50 ml of the donor's blood can be made However, by labelling red cells with radioactive isotopes it is possible to measure the survival of very small volumes of cells In investigations reported here approximately 1 ml of red cells were labelled either with the isotope ^{51}Cr or with ^{32}P In addition to determining whether the red cells of prospective donors are compatible, this method provides a very useful means of discovering more about the action of blood-group antibodies in vivo

Methods

Labelling of Red Cells

About 1 ml quantities of red cells were labelled either with ^{32}P or with ^{51}Cr The ^{32}P method was essentially that described by Reeve and Veall (1949) as modified by Chaplin (1954) The ^{51}Cr method was that described by Mollison and Veall (1955) using ^{51}Cr with a specific activity of 5–10 mC per mg , the amount of Cr per millilitre of red cells was 2–10 µg

When two samples of cells, one labelled with ^{51}Cr and the other with ^{32}P, were to be injected, either the suspensions were made up to 25 ml separately or, more commonly, one sample of cells was added to the other and made up to a total volume of 25 ml with sterile ice cold saline solution The cells were kept cold until the time of injection, and then 20 ml of the suspension was injected from a calibrated syringe

Expression of Results

In all the cases reported below (except cases 1 and 4) the red-cell volume was determined by injecting the subject's own red cells or other compatible red cells labelled with either ^{32}P or ^{51}Cr From this determination the expected number of incompatible cells was calculated In the figures reproduced below the numbers of surviving cells are expressed as percentages of the expected figure

In cases 1 and 4, in which no compatible cells were injected, the red cell volume was deduced from the number of incompatible cells at zero time, determined by extrapolating the slope of elimination to the time axis

In calculating the survival of cells labelled with ^{32}P it was assumed that 1% of ^{32}P left the cells in each ten-minute period after the injection (Reeve and Veall 1949) , survival was measured by this method only for periods not exceeding one hour

In calculating the survival of cells labelled with ^{51}Cr no correction for loss of chromium was made during the first hour after injection, because it is known that the loss in so short a period is too small to be measurable When the survival of ^{51}Cr labelled cells was followed for periods exceeding one hour after injection, corrections for chromium elution were made from data published by Mollison and Veall (1955)—i e , it was assumed that about 6% of Cr was lost during the first 24 hours after injection, and that thereafter Cr eluted from the red cells with a half-period of about 55 days

Serological Tests

Unless otherwise specified, the antibody titres reported below refer to the results of indirect anti globulin (Coombs) tests Halving dilutions of the recipient's serum, taken immediately before the injection, were incubated with a sample of the cells used for injection In cases 2–5 sensitisation took place only in the presence of complement , therefore fresh " neutral " serum was added to each tube of the titration After incubation with the patient's serum the cells were tested with a range of dilutions of anti globulin serum The anti globulin serum used was one which had previously been shown to contain anti beta globulin as well as anti gamma globulin (see Crawford et al 1955)

Enzyme-treated cells were used for detecting Lewis antibodies (cases 2–4) and to demonstrate the characteristics of a serum containing anti P (case 5) The enzyme ficin was used, and the tests were made according to directions supplied by Dr. R E Rosenfield

One drop of a 1% ficin solution (in Hendry's buffer of pH 7 4) was added to nine drops of a 2% suspension of red cells , after 15 minutes' incubation at 37°C the red cells were washed once in saline solution and resuspended to a 2% concentration in fresh saline solution Two drops of the red cell suspension were mixed with two drops of the patient's serum , the mixture was examined for hæmolysis after one hour at 37°C

In each case the patient's serum was also tested for its ability to agglutinate cells suspended in saline solution at room-temperature and at 37°C In some cases, after the cells had settled in the tube, 20% albumin was substituted for the supernatant serum saline mixture and half an hour later the deposit was examined microscopically for agglutinates (Dodge 1952)

Results

Great variations in the rate of destruction of red cells were observed when incompatible cells were injected, the destruction tended to follow certain definite patterns

Elimination of Most of the Injected Cells within Ten Minutes

This pattern was observed after injecting Fy(a+) cells into case 1, whose serum contained anti Fy^a, and was also observed after injecting Le(a+) cells into case 2, whose serum contained anti Le^a

Case 1 —A man, aged 48, suffering from hæmophilia, had been transfused many times, and his serum contained the blood group antibodies anti-Fy^a and anti Rh During a period when he was in relatively good health and at work he was given small amounts of incompatible cells so that their survival could be studied Fy(a+) Rh negative cells from the same donor were injected on two occasions, being labelled with ^{51}Cr on the first occasion and with ^{32}P on the second As shown in fig 1, essentially the same pattern of elimination was observed on both occasions—i e , after a lag of two or three minutes the cells rapidly left the circulation , in the following five minutes 50% were removed, and after 20 minutes only 10% were left The remainder were more slowly eliminated

The two injections of Fy(a+) cells were given at an interval of two weeks , there appeared to be no immune response to

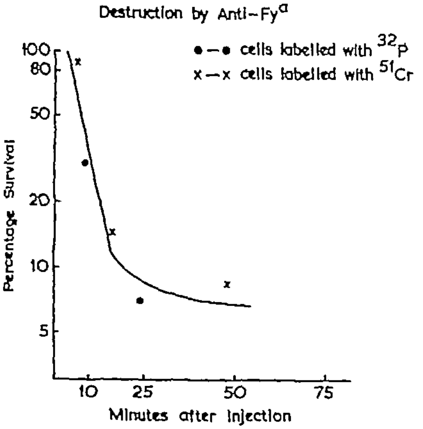

Fig. 1—Survival of Fy(a+) cells in case 1. The cells labelled with ^{32}P were injected two weeks after the cells labelled with ^{51}Cr; the same donor was used. The titre of anti-Fy^a was 1/8 on both occasions. The percentage survival is plotted on a logarithmic scale in this figure and in figs. 2-5 and 7.

the first injection, the titre of anti-Fy^a remaining at 1/8 throughout the period of the observations.

Case 2.—A man, aged 72, with subacute leukæmia received between May and July, 1954, blood from ten donors without reaction. In November, 1954, he was transfused with blood from two more donors (donors 11 and 12, see below). Four or five minutes after transfusion began he developed pain in the back, but this disappeared when the rate of the transfusion was slowed, and it did not reappear when the transfusion was speeded up. He was transfused with blood from four more donors (13, 14, 15, 16) during November without reaction, but on Dec. 1, after the transfusion of a further 250 ml. of blood (donor 17), he developed backache again, and the transfusion was discontinued. Shortly afterwards the patient passed urine containing hæmoglobin. Next day his serum was found to contain methæmalbumin, and his urine to contain methæmoglobin. During the next ten days he was transfused with five bottles of blood without incident.

On Dec. 16, 1 ml. of the fresh cells of donor 17, labelled with ^{51}Cr, was injected. The first sample, taken eight minutes after injection, contained only 20% of the expected count of cells. Further tests now showed that the patient's serum contained anti-Le^a and that donor 17 was Le(a+), as were donors 11 and 14.

A further test injection of Le(a+) cells (donor H. L.) was given when the anti-Le^a titre was 1/16: it was found that elimination was almost complete in ten minutes. When the numbers of surviving cells were plotted on a semi-logarithmic scale against time, it was observed that the points between about three and ten minutes fitted a straight line. This line, when extrapolated to 100% survival, crossed the time axis at about two and a half minutes, suggesting a short lag phase after injection (see fig. 2).

Le(a− b−) cells were relatively slowly eliminated—i.e., there was no significant change in their number during the few hours following injection. The survival of these cells was followed for two months, and it was found that their rate of elimination was only slightly greater than in normal recipients. It was presumed that the patient had a mild hæmolytic process, probably related to his leukæmia.

The patient's serum only weakly agglutinated Le(a+) cells. The antibody could be readily detected by the indirect antiglobulin test if the test was made in the presence of complement. The reactions were stronger when the patient's serum was incubated with cells at 37°C than when sensitisation was carried out at room temperature. After being heated to 56°C for twenty minutes the patient's serum no longer sensitised Le(a+) cells; its sensitising power was restored by the addition of fresh normal serum (lacking Le^a substance).

The antiglobulin reaction in this case (and in cases 3-5) did not depend on anti-gamma-globulin but on anti-beta-globulin in the rabbit serum. For example, the reaction was not inhibited by the addition of gamma-globulin but was inhibited by the addition of serum from a patient with agammaglobulinæmia (Crawford et al. 1955).

After treatment with ficin, Le(a+) cells were lysed by the patient's serum. Great variation was found among the reactions of Le(a+) cells from different donors; the cells could be classed as having 'strong' or 'weak' Lewis antigens, judged by their susceptibility to lysis and by their degree of sensitisation to an antiglobulin serum after exposure to the patient's serum. In comparative tests the cells of donor H. L. gave very weak reactions; nevertheless, as fig. 2 shows, they were very rapidly eliminated in this patient.

Rapid Elimination of a Proportion of the Injected Cells within Ten Minutes; Much Slower Elimination of the Remainder

This pattern was observed after injecting Le(a+) cells into cases 3 and 4, whose serum contained anti-Le^a. It was also observed after injecting P-positive cells into a patient with anti-P (case 5); in this case the elimination of the P-positive cells could not be prevented by warming the cells to 37°C before injection.

Case 3.—A woman, aged 19, had had severe hæmorrhage requiring transfusion at the time of parturition. She had never previously been transfused and had never been pregnant before. Her present infant (at the age of two weeks) was Le(a−) and had no Le^a substance in its saliva. The patient received blood (about 2500 ml.) from five donors and was noticed to be jaundiced next day. However, the possibility that the jaundice was related to the administration of blood was not seriously considered until ten days later. It was then found that the patient's serum contained anti-Le^a (titre 1/8) and that one of the five donors was Le(a+).

This patient's serum had the same general characteristics as the serum of case 2 but reacted less strongly in vitro with Le(a+) cells than did the serum of case 2. Similarly, when test injections of Le(a+) cells (donor H. L.) were given they were less rapidly eliminated (see fig. 2). During the ten minutes after the injection two-thirds of the cells were removed from the circulation; however, 20% of the cells were still present after 25 minutes, and no further decrease took place in the following 50 minutes. The cells had been labelled with ^{32}P, and their subsequent survival could not be estimated accurately; however, from the amount of ^{32}P present at 24 hours it was estimated that at least 10% of the cells were still present.

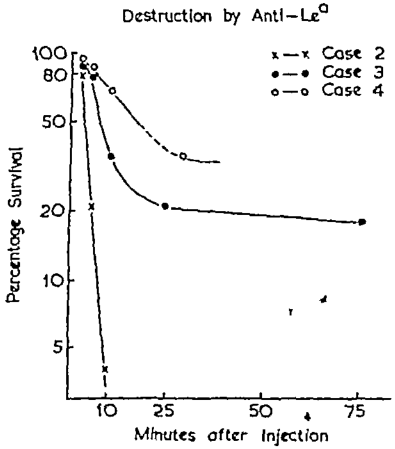

Fig. 2—Survival of Le(a+) cells from donor H. L. in cases 2-4. In case 4 the slope of elimination has been represented as flattening after 25 minutes because 27% of the cells were still present eight days later.

Case 4 —A woman, aged 35, who had never been transfused, was found to have anti Le^a in her serum during the course of her third pregnancy Four years later her serum reacted well in vitro at 37°C with cells from donors with "strong" Lewis antigens but poorly with cells from donors (such as H L) with "weak" Lewis antigens At this time, when the titre of anti Le^a was 1/1, she was injected with labelled Le(a+) cells (from donor H L as used in cases 2 and 3) During the 30 minutes after injection 65% of the cells were removed from the circulation (see fig 2), however, the remaining cells survived almost normally, with the result that three weeks after injection 23% of the total number injected were still present

Case 5 —A man, aged 70, admitted to hospital for trans urethral prostatectomy, had never previously been transfused In the course of selecting blood to hold in reserve during operation the patient's serum was found to agglutinate all samples of blood with which it was tested at room temperature Further investigation showed that the patient's serum contained an auto agglutinin acting weakly at room temperature, and an anti P agglutinin acting strongly at room temperature At 37°C the serum weakly agglutinated P positive cells and caused partial lysis of ficin treated P positive cells Fresh (but not heated) serum gave a weakly positive indirect anti globulin reaction with P positive cells (titre 1/2)

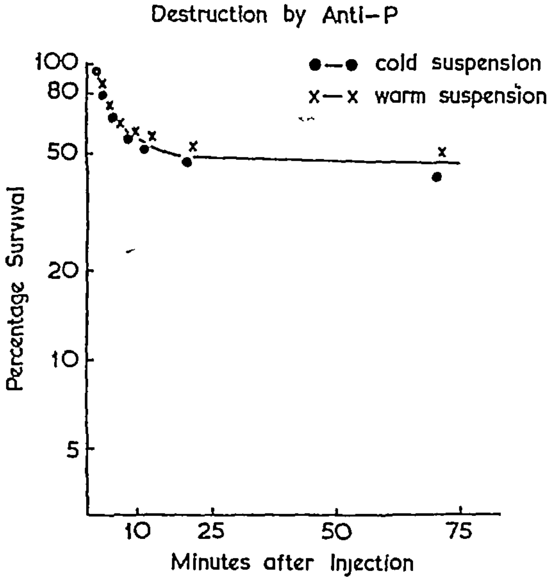

Fig 3—Survival of P positive cells in case 5 The cells injected as an ice-cold suspension were labelled with ^{32}P, those (from the same donor) injected as a warm suspension (39°C) were labelled with ^{51}Cr

The patient was transfused with P negative blood, and injections of labelled P positive cells were given On three separate occasions the pattern of elimination was essentially the same—namely, removal of about 50% of the injected cells in 10–15 minutes, followed by very much slower removal of the remainder For example, on one occasion the percentage of cells surviving 70 minutes after injection was 51% Next day the percentage survival was unchanged, after 9 days the number had fallen to 31%, and after 29 days to 17% Labelled P negative cells were found to survive normally

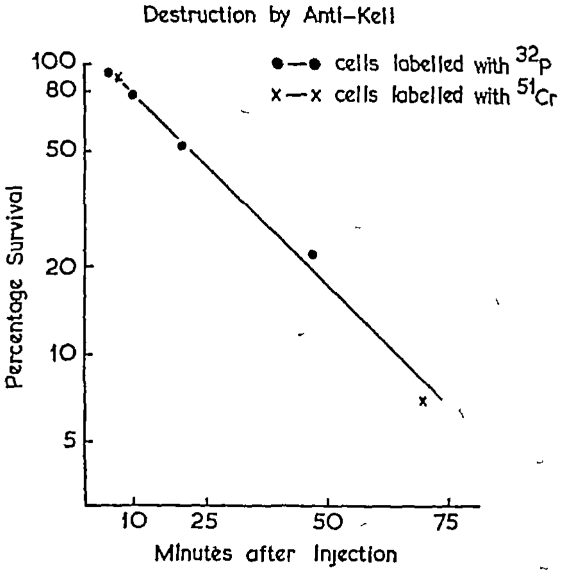

Fig 4—Survival of Kell positive cells in case 6 There was an interval of three days between the two injections, the titre of anti Kell was the same on both occasions, and the cells of the same donor were used

To discover whether the temperature of the suspension of P positive cells injected influenced their survival, the following experiment was made on two occasions The cells of a P positive donor were labelled with ^{32}P, suspended in ice cold saline solution, and kept in a bath at 0°C until injected Cells from the same donor were labelled with ^{51}Cr, suspended in warm saline solution, and kept in a bath at about 39°C until injected The warm suspension was rapidly injected into a vein, followed by a few ml of saline solution at 20°C, followed by the ice cold suspension The survival of the cells is illustrated in fig 3 Note that the cells injected at body temperature were eliminated just as rapidly during the first ten minutes as the cells injected as a cold suspension The same donor was used on both occasions, and close agreement was found between the results of the two tests—e g, 12 minutes after injection the results were as follows "warm" cells 56% and 57%, and "cold" cells 53% and 52% on the two occasions.

Constant Rate of Elimination with a Half-period of 20–30 Minutes

This mode of elimination was observed when Kell positive cells were injected into case 6, whose serum contained anti-Kell It was also observed when Rh positive cells were injected into two patients whose serum contained anti-Rh, one of these patients (case 1) is described in this section, the other (case 7) is described in a later section because initially she showed a different pattern of elimination

Case 6 —A woman with paroxysmal nocturnal hæmoglobinuria had been transfused many times, and her serum contained anti Kell The survival of Kell positive cells is illustrated in fig 4 Note that the number of surviving cells fitted a semilogarithmic plot, it appeared that there was a lag of about three minutes after injection before the cells

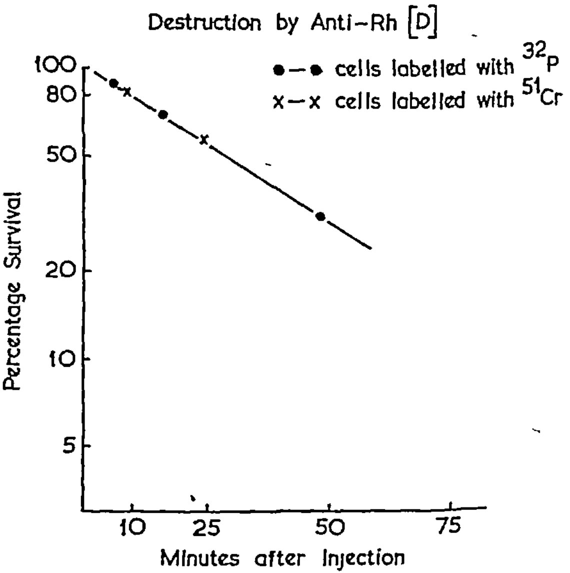

Fig 5—Survival of Rh-positive cells in case 1 The injections were given at an interval of two weeks, using red cells from the same donor On the first occasion the anti Rh titre was 1/64; on the second occasion it was 1/2000

started to disappear thereafter 50% were removed in 20 minutes. Kell positive cells were injected on two separate occasions, being labelled with ^{51}Cr the first time and with ^{32}P the second time three days later The results on the two occasions were essentially the same and the titre of anti Kell remained at 1/16 On the first occasion the number of injected cells decreased steadily over the 70 minutes following injection, only 7% being left at that time However next day 3-4% were still present; three days later they had all gone Kell negative cells survived normally in this patient

Case 1.—This was the patient already described above whose serum contained both anti Fy^a and anti Rh (—D) Rh positive (CDe/cDE) Fy(a—) cells were injected on two occasions, being labelled with ^{32}P the first time and with ^{51}Cr two weeks later The titre of Rh antibody rose considerably after the first injection, being 1/64 at the time of the first injection and 1/2000 at the time of the second injection. Despite this the rate of elimination was no more rapid on the second occasion (see fig 5) Note that the number of surviving cells, plotted on a logarithmic scale against time, fell upon a straight line; the time required for the removal of 50% of the cells was 28 minutes.

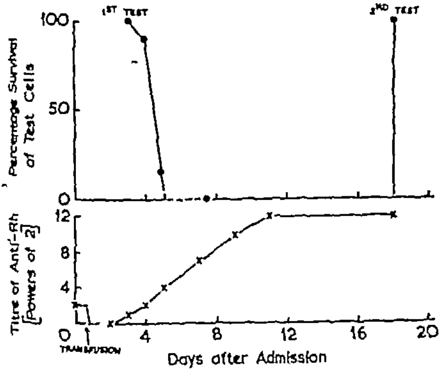

Fig. 6.—Changes in titre of anti-Rh and survival of labelled Rh-positive cells during 18 days following the transfusion of Rh-positive blood in case 7 The Rh-positive (CDe/CDe) cells injected three days after transfusion when the anti-Rh titre was 1/1 were eliminated relatively slowly (10% in 24 hours 90% in two days) The cells (from the same donor) injected 18 days after transfusion when the antibody titre was about 1/2000 were eliminated rapidly (half-period about 30 minutes)

Temporary Slowing of Rate of Elimination of Incompatible Cells, due to Adsorption of Antibody

After the transfusion of relatively large amounts of incompatible blood the antibody may all be adsorbed on to the incompatible cells In these circumstances the rate of elimination of a further transfusion of incompatible cells may be relatively slow If there is an immune response and the amount of antibody increases considerably, the incompatible cells may be rapidly eliminated, as in the following case

Case 7.—A woman, aged 58 with carcinoma of the rectum and abdominal metastases, had been transfused with Rh positive blood a year previously During an emergency operation she was transfused with 500 ml of Rh positive blood under the impression that she was Rh positive a 30-minute cross matching test in albumin had not revealed incompatibility Further testing showed that the patient was Rh negative and that her serum contained Rh antibody (indirect anti globulin test) Three days later her blood still contained circulating Rh positive red cells. This was demonstrated in two ways: (1) by showing that clumps of M cells were present, the donor being type M and the recipient type N; and (2) by showing that a small proportion of the patient s cells were strongly agglutinated by an anti globulin serum. Three days after the transfusion of 500 ml of Rh positive blood there was very little free anti Rh in the patient s serum (titre 1/1); a test injection of Rh positive cells (CDe/CDe) was given There was no change whatever in the count of the injected cells during the two and a half hours following the injection next day 90% were still present but on the following day only 14% were present (see fig 6) A test made two days later showed no trace of surviving cells This rapid decrease in the number of surviving cells coincided with the rapid increase in the amount of Rh antibody in the patient s serum. Fifteen days after the first test a second injection of Rh positive cells from the same donor was given, when the titre of Rh antibody was very high (1/2000) The cells were rapidly eliminated, 50% being removed in about 30 minutes the estimates fitted a semilogarithmic plot

Constant Rate of Elimination with a Half-period of Several Days

In some instances the amount of antibody or its character appears to be inadequate to bring about the rapid elimination of incompatible cells In the following case despite the presence in the patient's serum of anti-c in a titre of 1/16 c-positive cells were eliminated relatively slowly (50% in 5–7 days)

Case 8.—A woman aged 41 was admitted after having had a considerable hæmatemesis presumably from an acute gastric erosion. She had had three pregnancies six months previously she had been transfused with blood from two donors. Preliminary matching tests showed that her serum contained anti-c. She was transfused with blood from three Rh positive donors without any untoward reaction but rechecking showed that one of the donors was c-positive Testing of the patient s blood eight hours after transfusion showed that most, or all of these cells were present (positive direct anti-globulin test) The anti-c which had been easily demonstrable in the patient s serum before transfusion (titre 1/16) was now extremely weak (titre 1/2) An injection of labelled c positive cells (cde/cde) was given the survival of these cells is illustrated in fig 7 Note that for the first 14 days the numbers of surviving cells, when plotted on a semi logarithmic scale against time fall upon a straight line 50% of the cells being eliminated in just over seven days. After 14 days the slope of elimination became a little steeper perhaps because the patient had a mild immune response There was no evidence of any further bleeding during the period of the observations

Thirty-six days after she had received the transfusion of incompatible blood, and at a time when her circulation contained no trace of surviving c positive cells she was given a further test injection of c positive cells from the same donor (cde/cde) whose cells had been injected previously The survival of these cells is also shown in fig 7 Note that

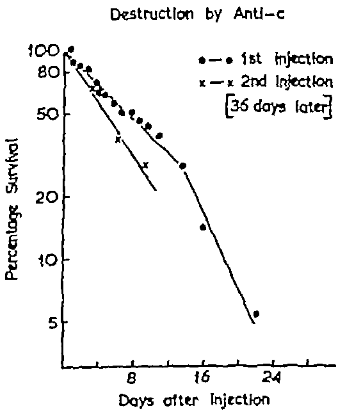

Fig. 7.—Survival of c-positive cells in case 7 Note that the time scale is in days. The first injection of labelled cells was given 12 hours after the patient had been transfused with 500 ml. of c-positive blood The second injection was given when all the transfused c-positive cells had been eliminated.

elimination was only slightly more rapid than on the first occasion, 50% of the cells being eliminated in about five days The titre of anti-c at the time of the first injection was 1/2, at the time of the second injection it was 1/8–1/16

Elimination Unaffected by Non-specific Cold Agglutinins

There is a good deal of evidence that when cold agglutinins, capable of reacting at room temperature but incapable of reacting at 37°C, are present in the serum they do not influence the survival of transfused red cells. The following case provides further evidence

Case 9 —A young man with acute leukæmia had been transfused eight times during the previous four months His serum agglutinated all red cells except his own However, the reactions took place only at room-temperature and not at 37°C The indirect anti globulin test was negative The red cells of a donor whose cells were strongly agglutinated by the patient's serum at room temperature were injected as a cold suspension, their survival was within normal limits for the three days during which it was followed

Discussion

Radioactive phosphorus and radioactive chromium appear to be equally satisfactory red-cell labels for investigations lasting only an hour However, ^{51}Cr is evidently more suitable if the survival of the red cells is to be followed longer There is evidence that, provided the dose of chromium does not exceed about 25 µg per ml. of red cells, their survival is unaffected (Donohue et al 1955) In the present work the dosage never exceeded 10 µg per ml and was sometimes as low as 2 µg per ml of red cells For this particular type of work it is evidently a great advantage to use ^{51}Cr of very high specific activity, such as that produced by the Szilard Chalmers reaction (see Mollison and Veall 1955)

The present observations provide further evidence that, when ^{51}Cr-labelled red cells are broken down, the chromium is not re utilised by other cells (Ebaugh et al 1953) For example, in one case on the day following the injection of labelled incompatible cells no radioactivity was detected in a sample of red cells taken from the patient, the plasma contained about 1% of the injected radioactivity When ^{32}P labelled red cells were rapidly destroyed, a small fraction of the ^{32}P appeared to label other red cells, with the result that about 1–3% of the injected activity remained in the blood

In all the cases described here the volume of incompatible cells injected was about 1 ml, no untoward symptoms were noted, even when all the injected cells were destroyed within ten minutes

There appear to be two main patterns of elimination of incompatible cells The characteristics of the first type of elimination are as follows after injection there is a brief lag-phase, lasting about two and a half minutes, before destruction begins Then a large proportion of the cells undergo rapid destruction, presumably by intravascular lysis The proportion of cells destroyed rapidly varies from 50 to 100% Case 2 represents one extreme, 90% of the injected cells having been destroyed in five minutes At the other extreme lie cases 4 and 5, in which 50% of the cells were destroyed in about 15 minutes and the remainder survived for three weeks or more (see table) It must be concluded that within a population of red cells susceptibility to destruction by the antibodies anti-Le^a and anti-P varies widely Apparently, however, relative insensitivity may be overcome if the antibody is strong enough, this is well shown by fig 2

O'Brien et al (1954) report in dogs findings which are similar in some respects to those reported here Thus, in dogs whose serum contains canine anti A, dog A_1 cells are very rapidly eliminated, but, when A_2 cells are transfused, only about 50% are rapidly destroyed, the remainder being slowly eliminated over one or two months

In the second main pattern of destruction, illustrated in figs 4 and 5, the red cells are removed from the circulation with a half-period of 20–30 minutes, and the points appear to fit a semilogarithmic plot Dr N Veall (personal communication) suggests that this may represent the time required for half the cells to pass through the spleen He points out that, if 3% of the circulating blood passes through the spleen each minute, and if the blood in passing is cleared completely of incompatible cells, it will take about 25 minutes to remove half the incompatible cells from the circulation

DESTRUCTION OF RED CELLS

Case no	Specific antibody	Time taken for destruction of	
		50 % of cells (min)	90 % of cells
1	anti Fy^a	5	20 min.
2*	anti Le^a	1¼	5 min
3*	anti Le^a	5½	More than 24 hr
4*	anti Le^a	16	More than 3 wk
5	anti P	15	More than 4 wk.

* The same donor (H L) was used in these three cases
The time taken for destruction was measured from a point 2½ minutes after injection (see text)

When the Rh antibody titre is as high as 1/2000, destruction is no more rapid than when it is as low as 1/64 (case 1, see fig 5) It must be supposed that, in this type of destruction of red cells, provided the red cells are "saturated" with antibody, the rate of elimination cannot be raised further by increasing the amount of antibody However, when the titre of Rh antibody is low (e g, 1/2) the red cells may be destroyed considerably more slowly, as in case 7 (see fig 6)

The relatively slow destruction of c positive cells in case 8 was rather surprising Before the transfusion of 500 ml of c-positive blood the titre of anti-c was 1/16, the slow elimination of the incompatible cells of this blood, and of the 1 ml of labelled cells injected 12 hours later, was thought to be due to temporary absorption of antibody, the titre of free antibody having fallen to 1/2 However, 36 days after the transfusion, when the titre of anti-c had risen again to 1/16, 1 ml of c-positive cells was eliminated almost equally slowly

Although in this last patient (case 8) the elimination of incompatible cells was scarcely more rapid when 1 ml was injected than when a whole bottle of blood was transfused, it would be unwise to conclude that the volume of injected cells normally has little influence on the rate of elimination Indeed, experimental work in dogs has shown that, if two incompatible transfusions are given in succession, the second lot of red cells is less rapidly destroyed, evidently because the amount of antibody in the recipient's circulation has been reduced (Christian et al 1951) In practice the fact that a small volume of incompatible cells may be more rapidly eliminated than a large volume does not impair the value of the test proposed here The prime object of the test is to obtain evidence for or against the compatibility of the cells of a given donor, and for this it is only necessary to discover whether or not there is any departure from the normal rate of elimination

When incompatibility is due to antibodies which are hæmolytic in vitro, it is to be expected that intravascular lysis will occur in vivo Anti Le^a and anti-P have been reported as being lytic in vitro (Andresen 1950, Rosenfield and Vogel 1951, Moureau 1945) The anti-Le^a and anti P sera encountered in the present work would hæmolyse enzyme-treated cells but not untreated cells in vitro In vivo, both these antibodies very rapidly eliminated a large proportion of the injected cells In case 2 the transfusion of Le(a+) blood was followed by hæmoglobinuria, as in a previously reported case of "suspected incompatibility due to anti Le^a" (Brendemoen and Aas 1952)

The very rapid elimination of labelled cells by anti Fy^a was unexpected, although hæmoglobinuria has been reported in a case of incompatibility due to this antibody (Wiener 1954)

If it is true that anti Rh and anti Kell normally cause extravascular destruction as suggested by the present observations, it might seem that these antibodies should not cause hæmoglobinæmia Intravascular hæmolysis has been reported after the transfusion of Rh positive blood to patients with Rh antibody in their serum (Vogel et al 1943) and after the transfusion of Kell positive blood to a patient with anti Kell (Young 1954) In these cases it must be supposed either that the antibody has become capable of bringing about intravascular hæmolysis or that when extravascular destruction is very rapid, there is some spill over of the hæmoglobin into the plasma

In all the cases reported here in which injected red cells were destroyed at an increased rate the incompatibility could have been predicted from the results of the anti globulin test—i e the patient's serum at 37°C, sensitised the donor's cells to an anti globulin serum However, the reactions were much stronger with some anti globulin sera than with others This applied particularly to cells sensitised with anti Le^a and anti P As reported here, these antibodies are not gamma globulins and their detection depends on the presence of anti beta globulin in the anti globulin sera Some anti globulin sera contain relatively little anti beta globulin and are unsuitable for detecting these particular blood group antibodies (Crawford et al 1955)

It should be emphasised that the presence of anti Le and anti P could be detected by the anti globulin test only if the patient's fresh serum was used It follows that in cross-matching tests if a fresh sample of serum is not available fresh normal serum should be added to the serum-cell mixtures Plasma should not be used anticoagulants being anticomplementary

Dacie (1950) has shown that the incomplete cold antibody found in normal serum and the incomplete antibody found in the cold type of acquired hæmolytic anæmia are adsorbed on to red cells only in the presence of complement moreover red cells sensitised with these antibodies react with anti globulin sera to which gamma globulin has been added The present observations show that in these respects anti Le^a and anti P are similar

Summary

The survival of transfused cells can be estimated by using volumes of cells as small as 1 ml ^{32}P is suitable as a label when the survival is to be followed for an hour or so, but ^{51}Cr must be used when survival is to be followed for days or weeks

When incompatible red cells were injected their elimination followed one of two main patterns

(1) In the first pattern 50–100% of the cells were destroyed within ten minutes; cells surviving at the end of this period were much more slowly destroyed This pattern of elimination was seen when cells were injected into patients whose serum contained anti Fy^a anti Le^a or anti P

(2) In the second pattern the cells were eliminated at a steady rate with a half period of 20–30 minutes. This pattern was seen when cells were injected into patients whose serum contained anti Rh or anti Kell.

It is suggested that measurement of the rate of elimination of small volumes of injected red cells may be a useful biological test in cases in which the interpretation of compatibility tests in vitro is difficult

In all cases in which red cells were rapidly destroyed in vivo the indirect anti globulin test was positive in vitro However in cases where the serum contained anti Le^a or anti P the cells were sensitised only if incubated with fresh serum Moreover in these cases it was shown that the reaction of the sensitised cells with anti globulin serum depended not on anti gamma globulin but upon anti beta globulin Some anti globulin sera were unsuitable for the detection of these antibodies.

We are indebted to Dr Eloise R Giblett for her assistance in these investigations Dr J V Dacie and Dr J H Crookston for calling our attention to many of these cases; Prof. J McMichael Dr C L Cope and Prof J M Browne for permission to investigate patients under their care Dr J D James Dr P B Booth, and Dr G Plaut, of the North London Blood Transfusion Centre for their help on numerous occasions in collecting blood from donors; and Dr G H. Grant for serum from a patient with agammaglobulinæmia

INCREASED EXCRETION OF ALDOSTERONE IMMEDIATELY AFTER OPERATION

J G LLAURADO
M.D Barcelona
LECTURER IN EXPERIMENTAL SURGERY IN THE UNIVERSITY OF OTAGO DUNEDIN NEW ZEALAND

> "The urine of man is one of the animal matters that have been the most examined by chemists and of which the examination has at the same time furnished the most singular discoveries to chemistry and the most useful application to physiology as well as the art of healing (De Fourcroy 1801)

IT is well known that surgical trauma is followed by a positive sodium balance and a negative potassium balance. Several hypotheses have been formulated (Wilkinson et al 1950 Winfield et al 1951 Schilling et al. 1953 Le Quesne 1953) to explain the increased excretion of K^+ Some workers have postulated that the adrenal cortex plays the chief rôle in this alteration of electrolyte metabolism but hitherto evidence for this hypothesis has been lacking In recent years several reports have been published of the occurrence of a sodium retaining factor in some human urine but neither the salt-conserving action of this factor nor indeed the rôle of the adrenal cortex in controlling electrolyte balance in healthy people can be explained by the activity of deoxycortone (Luetscher et al 1952) which until recently was the only steroid known to possess such sodium retaining properties in high degree The discovery by Grundy et al (1952) of a new hormone of the adrenal cortex now called aldosterone which has the ability to increase greatly both Na^+ retention and K^+ excretion by the kidney the subsequent isolation of this hormone (Simpson et al 1953) and the determination of its chemical structure (Simpson et al 1954) have given a new impetus to the investigation of clinical disturbances associated with Na^+ retention and increased K^+ excretion

In a previous paper (Cope and Llaurado 1954) it was reported that aldosterone (electrocortin) was present in large amounts in the urine of a patient suffering K^+ loss (Evans and Milne 1954) Since the communication by Conn (1954) it seems clear that the case was one of primary aldosteronism elimination was only slightly more rapid than on the first occasion, 50% of the cells being eliminated in about five days The titre of anti-c at the time of the first injection was 1/2, at the time of the second injection it was 1/8–1/16

Elimination Unaffected by Non-specific Cold Agglutinins

There is a good deal of evidence that when cold agglutinins, capable of reacting at room temperature but incapable of reacting at 37°C, are present in the serum they do not influence the survival of transfused red cells The *following case provides further evidence*

Case 9 —A young man with acute leukæmia had been transfused eight times during the previous four months His serum agglutinated all red cells except his own However, the reactions took place only at room temperature and not at 37°C The indirect anti globulin test was negative The red cells of a donor whose cells were strongly agglutinated by the patient's serum at room temperature were injected as a cold suspension, their survival was within normal limits for the three days during which it was followed

Discussion

Radioactive phosphorus and radioactive chromium appear to be equally satisfactory red-cell labels for investigations lasting only an hour However, ^{51}Cr is evidently more suitable if the survival of the red cells is to be followed longer There is evidence that, provided the dose of chromium does not exceed about 25 µg per ml. of red cells, their survival is unaffected (Donohue et al 1955) In the present work the dosage never exceeded 10 µg per ml and was sometimes as low as 2 µg per ml of red cells For this particular type of work it is evidently a great advantage to use ^{51}Cr of very high specific activity, such as that produced by the Szilard Chalmers reaction (see Mollison and Veall 1955)

The present observations provide further evidence that, when ^{51}Cr-labelled red cells are broken down, the chromium is not re utilised by other cells (Ebaugh et al 1953) For example, in one case on the day following the injection of labelled incompatible cells no radioactivity was detected in a sample of red cells taken from the patient, the plasma contained about 1% of the injected radioactivity When ^{32}P labelled red cells were rapidly destroyed, a small fraction of the ^{32}P appeared to label other red cells, with the result that about 1–3% of the injected activity remained in the blood

In all the cases described here the volume of incompatible cells injected was about 1 ml, no untoward symptoms were noted, even when all the injected cells were destroyed within ten minutes

There appear to be two main patterns of elimination of incompatible cells The characteristics of the first type of elimination are as follows after injection there is a brief lag phase, lasting about two and a half minutes, before destruction begins Then a large proportion of the cells undergo rapid destruction, presumably by intravascular lysis The proportion of cells destroyed rapidly varies from 50 to 100% Case 2 represents one extreme, 90% of the injected cells having been destroyed in five minutes At the other extreme lie cases 4 and 5, in which 50% of the cells were destroyed in about 15 minutes and the remainder survived for three weeks or more (see table) It must be concluded that within a population of red cells susceptibility to destruction by the antibodies anti-Le^a and anti-P varies widely Apparently, however, relative insensitivity may be overcome if the antibody is strong enough, this is well shown by fig 2

O'Brien et al (1954) report in dogs findings which are similar in some respects to those reported here Thus, in dogs whose serum contains canine anti A, dog A$_1$ cells are very rapidly eliminated, but, when A$_2$ cells are transfused, only about 50% are rapidly destroyed, the remainder being slowly eliminated over one or two months

In the second main pattern of destruction, illustrated in figs 4 and 5, the red cells are removed from the circulation with a half-period of 20–30 minutes, and the points appear to fit a semilogarithmic plot Dr N Veall (personal communication) suggests that this may represent the time required for half the cells to pass through the spleen He points out that, if 3% of the circulating blood passes through the spleen each minute, and if the blood in passing is cleared completely of incompatible cells, it will take about 25 minutes to remove half the incompatible cells from the circulation

DESTRUCTION OF RED CELLS

Case no	Specific antibody	Time taken for destruction of —	
		50% of cells (min.)	90% of cells
1	anti Fy^a	5	20 min
2*	anti Le^a	$1\frac{1}{2}$	5 min
3*	anti Le^a	$5\frac{1}{2}$	More than 24 hr
4*	anti Le^a	16	More than 3 wk
5	anti P	15	More than 4 wk

* The same donor (H L) was used in these three cases

The time taken for destruction was measured from a point $2\frac{1}{2}$ minutes after injection (see text)

When the Rh antibody titre is as high as 1/2000, destruction is no more rapid than when it is as low as 1/64 (case 1, see fig 5) It must be supposed that, in this type of destruction of red cells, provided the red cells are "saturated" with antibody, the rate of elimination cannot be raised further by increasing the amount of antibody However, when the titre of Rh antibody is low (e g, 1/2) the red cells may be destroyed considerably more slowly, as in case 7 (see fig 6)

The relatively slow destruction of c positive cells in case 8 was rather surprising Before the transfusion of 500 ml of c-positive blood the titre of anti-c was 1/16, the slow elimination of the incompatible cells of this blood, and of the 1 ml of labelled cells injected 12 hours later, was thought to be due to temporary absorption of antibody, the titre of free antibody having fallen to 1/2 However, 36 days after the transfusion, when the titre of anti c had risen again to 1/16, 1 ml of c positive cells was eliminated almost equally slowly

Although in this last patient (case 8) the elimination of incompatible cells was scarcely more rapid when 1 ml was injected than when a whole bottle of blood was transfused, it would be unwise to conclude that the volume of injected cells normally has little influence on the rate of elimination Indeed, experimental work in dogs has shown that, if two incompatible transfusions are given in succession, the second lot of red cells is less rapidly destroyed, evidently because the amount of antibody in the recipient's circulation has been reduced (Christian et al 1951) In practice the fact that a small volume of incompatible cells may be more rapidly eliminated than a large volume does not impair the value of the test proposed here The prime object of the test is to obtain evidence for or against the compatibility of the cells of a given donor, and for this it is only necessary to discover whether or not there is any departure from the normal rate of elimination

When incompatibility is due to antibodies which are hæmolytic in vitro, it is to be expected that intravascular lysis will occur in vivo Anti Le^a and anti-P have been reported as being lytic in vitro (Andresen 1950, Rosenfield and Vogel 1951, Moureau 1945) The anti Le^a and anti P sera encountered in the present work would hæmolyse enzyme treated cells but not untreated cells in vitro In vivo, both these antibodies very rapidly eliminated a large proportion of the injected cells In case 2 the transfusion of Le(a+) blood was followed by hæmoglobinuria, as in a previously reported case of "suspected incompatibility due to anti-Le^a" (Brendemoen and Aas 1952)

The very rapid elimination of labelled cells by anti Fy^a was unexpected, although hæmoglobinuria has been reported in a case of incompatibility due to this antibody (Wiener 1954)

If it is true that anti Rh and anti Kell normally cause extravascular destruction, as suggested by the present observations, it might seem that these antibodies should not cause hæmoglobinæmia. Intravascular hæmolysis has been reported after the transfusion of Rh positive blood to patients with Rh antibody in their serum (Vogel et al 1943) and after the transfusion of Kell positive blood to a patient with anti Kell (Young 1954). *In these cases it must be supposed either that the* antibody has become capable of bringing about intravascular hæmolysis or that when extravascular destruction is very rapid there is some spill over of the hæmoglobin into the plasma.

In all the cases reported here in which injected red cells were destroyed at an increased rate the incompatibility could have been predicted from the results of the anti globulin test—i.e. the patient's serum, at 37°C sensitised the donor's cells to an anti globulin serum. However the reactions were much stronger with some anti globulin sera than with others. This applied particularly to cells sensitised with anti Le^a and anti P. As reported here, these antibodies are not gamma globulins and their detection depends on the presence of anti beta globulin in the anti globulin sera. Some anti globulin sera contain relatively little anti beta globulin and are unsuitable for detecting these particular blood group antibodies (Crawford et al 1955).

It should be emphasised that the presence of anti Le^a and anti P could be detected by the anti globulin test only if the patient's fresh serum was used. It follows that in cross matching tests if a fresh sample of serum is not available, fresh normal serum should be added to the serum-cell mixtures. Plasma should not be used, anticoagulants being anticomplementary.

Dacie (1950) has shown that the incomplete cold antibody found in normal serum and the incomplete antibody found in the cold type of acquired hæmolytic anæmia are adsorbed on to red cells only in the presence of complement; moreover red cells sensitised with these antibodies react with anti globulin sera to which gamma globulin has been added. The present observations show that in these respects anti Le^a and anti P are similar.

Summary

The survival of transfused cells can be estimated by using volumes of cells as small as 1 ml. ^{32}P is suitable as a label when the survival is to be followed for an hour or so but ^{51}Cr must be used when survival is to be followed for days or weeks.

When incompatible red cells were injected their elimination followed one of two main patterns:

(1) In the first pattern 50–100% of the cells were destroyed within ten minutes; cells surviving at the end of this period were much more slowly destroyed. This pattern of elimination was seen when cells were injected into patients whose serum contained anti Fy^a, anti Le^a or anti P.

(2) In the second pattern the cells were eliminated at a steady rate with a half period of 20–30 minutes. This pattern was seen when cells were injected into patients whose serum contained anti Rh or anti Kell.

It is suggested that measurement of the rate of elimination of small volumes of injected red cells may be a useful biological test in cases in which the interpretation of compatibility tests in vitro is difficult.

In all cases in which red cells were rapidly destroyed in vivo the indirect anti globulin test was positive in vitro. However in cases where the serum contained anti Le^a or anti P the cells were sensitised only if incubated with *fresh* serum. Moreover in these cases it was shown that the reaction of the sensitised cells with anti globulin serum depended not on anti gamma globulin but upon anti beta globulin. Some anti globulin sera were unsuitable for the detection of these antibodies.

We are indebted to Dr Eloise R Giblett for her assistance in these investigations; Dr J V Dacie and Dr J H Crookston for calling our attention to many of these cases; Prof J McMichael, Dr C L Cope and Prof J M Browne for permission to investigate patients under their care. Dr J D James Dr P B Booth and Dr G Plaut of the North London Blood Transfusion Centre for their help on numerous occasions in collecting blood from donors and Dr G H Grant for serum from a patient with agammaglobulinæmia.

INCREASED EXCRETION OF ALDOSTERONE IMMEDIATELY AFTER OPERATION

J G LLAURADO
M.D Barcelona
LECTURER IN EXPERIMENTAL SURGERY IN THE UNIVERSITY OF OTAGO DUNEDIN NEW ZEALAND

> The urine of man is one of the animal matters that have been the most examined by chemists and of which the examination has at the same time furnished the most singular discoveries to chemistry and the most useful application to physiology as well as the art of healing. (De Fourcroy 1801)

It is well known that surgical trauma is followed by a positive sodium balance and a negative potassium balance. Several hypotheses have been formulated (Wilkinson et al 1950 Winfield et al 1951 Schilling et al 1953 Le Quesne 1953) to explain the increased excretion of K$^+$. Some workers have postulated that the adrenal cortex plays the chief rôle in this alteration of electrolyte metabolism, but hitherto evidence for this hypothesis has been lacking. In recent years several reports have been published of the occurrence of a sodium retaining factor in some human urine but neither the salt-conserving action of this factor nor indeed the rôle of the adrenal cortex in controlling electrolyte balance in healthy people can be explained by the activity of deoxycortone (Luetscher et al 1952) which until recently was the only steroid known to possess such sodium retaining properties in high degree. The discovery by Grundy et al (1952) of a new hormone of the adrenal cortex now called aldosterone which has the ability to increase greatly both Na$^+$ retention and K$^+$ excretion by the kidney the subsequent isolation of this hormone (Simpson et al 1953) and the determination of its chemical structure (Simpson et al 1954) have given a new impetus to the investigation of clinical disturbances associated with Na$^+$ retention and increased K$^+$ excretion.

In a previous paper (Cope and Llaurado 1954) it was reported that aldosterone (electrocortin) was present in large amounts in the urine of a patient suffering K$^+$ loss (Evans and Milne 1954). Since the communication by Conn (1954) it seems clear that the case was one of primary aldosteronism.

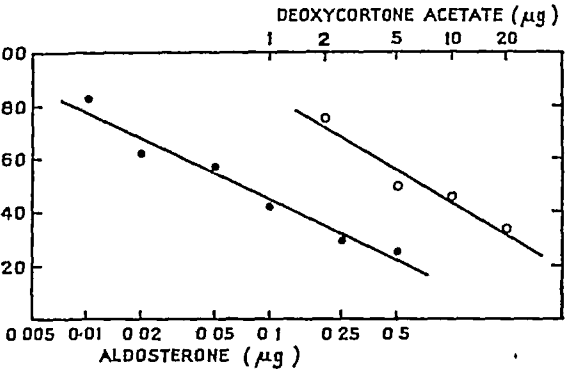

Fig 1—Effect of aldosterone and deoxycortone acetate on Na^+/K^+ ratio percentage of control Note linear relationship between log-dose and fall of Na^+/K^+ ratio percentage Aldosterone proves to be 100 times as strong as deoxycortone.

In the light of these facts it seemed important to determine whether the well-known phenomenon of K^+ loss following surgical trauma could also be explained by increased secretion of the electrolyte-regulating corticoid (presumably aldosterone) In the work presented here a search was made for this corticoid in the urine of patients before and at various stages after surgical operation This paper deals only with the results obtained before and immediately after operation A brief preliminary account of the results has been published (Llaurado 1954)

Methods

The methods of extracting aldosterone from urine and of estimating it by bio assay have been fully described previously (Cope and Llaurado 1954) The only difference introduced here is that ordinary Na^+ and K^+ have been used as loading injections to the rats, instead of radioactive $^{24}Na^+$ and $^{42}K^+$, since it has been statistically shown (Cope and Llaurado 1955) that the same degree of accuracy and sensitivity of the method can be reached by using non radioactive materials In the experiments reported here adult patients were chosen to include members of either sex with various clinical conditions and submitted to operations of various grades of severity Twenty four hour samples of urine were collected without preservative, the first before operation, and the second during the twenty four hours immediately after operation When there was anuria for the twenty four hours after operation, the next twenty-four hour specimen was taken as immediate postoperative collection No distinction was made between urine passed spontaneously by the patient and urine obtained by catheter

For injections into rats the dry extract was dissolved in 20% ethanol in water, the volume being so chosen that the dose to be injected (three hours *) into each rat was contained in 0 1 ml of solution.

The sodium and potassium were estimated in human urine in the aqueous phase of urine after extraction This procedure was adopted because the small amount of urine passed by the postoperative patient in twenty four hours made it advisable not to reduce the amount of urine before steroid extraction Preliminary experiments showed that the amount of steroid solvent left in the urine does not produce any interference at the flame, the results being the same as those obtained with urine before any manipulation An 'Eel' flame photometer was used for all Na^+ and K^+ estimations

Results

ASSAYS WITH CRYSTALLINE ALDOSTERONE

To obtain a standard of reference, bio assays were made with known quantities of pure crystalline aldosterone, kindly made available by Prof T Reichstein of Basle A linear relationship (fig 1) was found between percentage of Na^+/K^+ ratio response and log dose of aldosterone in a range from 0 01 μg to 0 5 μg Statistical data are tabulated in table I The new steroid proved to be 100 times as active (fig 1) as deoxycortone acetate (effective dose 2–20 μg) when assayed by the same method, and this result is in complete agreement with the earlier data published by Simpson and Tait (1953)

Some workers (Desaulles et al 1953, Swingle et al 1954) have suggested that aldosterone differs both quantitatively and qualitatively from deoxycortone acetate in the way in which it acts on electrolyte metabolism The present results, however, do not support this assertion, because the difference of slopes of regression lines of aldosterone and deoxycortone acetate do not differ significantly when analysed statistically, and favour the view that they are only quantitatively different.

Stability of Aldosterone in water alcohol solutions —Swingle et al (1954) reported that aldosterone retains the same biological activity when kept in 95% ethanol solution. In the present experiments a solution of aldosterone in 20% ethanol in water retained complete biological activity after being kept six weeks in the refrigerator

Recovery of aldosterone from human urine —Aldosterone was added to pooled human urine, the usual method of extraction was used, and the results were compared with the same volume of analogous urine as a blank An average recovery of 20% was obtained as estimated by its biological activity This percentage of recovery is about the same as that obtained when a commercially available adrenal cortical extract ('Eucortone') was added to human urine and assayed by the same method (Cope and Llaurado 1954) Very similar values for aldosterone recovery are reported by Mills (1954)

TABLE I—PARAMETERS OF REGRESSION LINES OF ALDOSTERONE AND DEOXYCORTONE ASSAYS

Parameter	Aldosterone	Deoxycortone
Slope = $\lvert b \rvert$	32 95	39 30
S D.L *	4 69	5 59
S E $_b$†	3 26	7 55
$L = \frac{1}{\lambda} = \frac{\lvert b \rvert}{S D L}$	6 90	7 04
r (coefficient of correlation)	–0 98	–0 96
No of rats used	68 (and 25 controls)	57 (and 43 controls)

$$* S D L = \sqrt{\frac{\Sigma (y - y \text{ calc })^2}{N-2}} = \text{standard deviation about the line}$$

$$† S E_b = \frac{S D L}{\sqrt{\Sigma (x - \bar{x})^2}} = \text{standard error of the slope}$$

$$x = \log X \text{ (dose assayed)}$$

ASSAYS WITH EXTRACTS OF URINE

Six patients have been studied so far Some activity was found in the urine of some patients on the day before operation, but others showed none From the point of view of adrenal cortex activity these patients before operation can be considered as "normal," and the finding of activity in these conditions agrees with previous results reported by Chart and Shipley (1953), Cope and Llaurado (1954), Luetscher et al (1954), and Venning et al (1954)

The extracts from urine obtained after operation invariably showed an increased sodium-retaining activity compared with the level before operation The activity levels before and after operation are shown in table II The difference between preoperative and postoperative activity is statistically highly significant ($P < 0\ 001$, determined by Student's t test)

Table II shows also the twenty-four-hour output expressed as micrograms of aldosterone after operation, calculated from the regression line (fig 1) and corrected for percentage of extraction recovery The results range from 0 14 μg to 2 70 μg daily of aldosterone excretion with an average output of 1 11 μg daily

---

[*] A three-hour dose is one-eighth of the extract obtained from a twenty four hour specimen of urine

TABLE II—COMPARATIVE DATA OF PATIENTS STUDIED BEFORE AND AFTER OPERATION

(Values under 100 indicate aldosterone activity in assayed urine) *

Case no.	Sex	Diagnosis	Operation	Aldosterone activity		24 hour output equivalent in µg. of aldosterone †		Volume of 24 hour urine (ml.)		Urine Na+ (m eq. per litre)		Urine K+ (m eq. per litre)	
				Preoperative	Postoperative	Preop	Postop	Preop	Postop	Preop	Postop	Preop	Postop
1	F	Biliary lithiasis	Cholecystectomy	101.7 ± 28.4	71.[illegible] ± 20.3		0.50	520	190	‡	‡	‡	‡
2	F	Inguinal hernia	Herniorrhaphy	110.0 ± 30.4	73.5 ± 24.1		0.43	980	190	‡	40.0	‡	200.0
3	M	Pulmonary tuberculosis	Thoracoplasty	78.8 ± 31.0	52.3 ± 1[illegible]	0.30	2.28	1300	270	111.3	79.4	48.3	124.0
4	F	Pulmonary tuberculosis	Lobectomy	99.0 ± 22.1	70.0 ± 16.0		0.64	1890	240	30.4	23.0	19.6	82.0
5	M	(?) Lung cancer	Lobectomy	96.6 ± 1[illegible].0	92.5 ± 17.0		0.14	1380	275	50.0	46.0	25.0	110.4
6	M	Œsophageal cancer	Œsophagojejunostomy	77.0 ± 18.2	50.1 ± 11.3	0.41	2.70	970	780	34.0	10.0	33.0	104.0

* Mean ± standard error.—S.E. calculated as follows

$$S.E. = \left[\frac{\frac{s_c}{\sqrt{n_c}}\,100}{m_c} + \frac{\frac{s_x}{\sqrt{n_x}}\,100}{m_x}\right]\frac{\frac{100\,m_x}{m_c}}{100}; \quad \text{where:}$$

$$\left.\begin{array}{l} s_c = \text{S.D. of control set}\\ s_x = \text{S.D. of unknown set}\end{array}\right\} = \sqrt{\Sigma\frac{(x-n)^2}{n}}$$

n_c = no. of rats in control set

n_x = no. of rats in unknown set

m_c = mean of control set

m_x = mean of unknown set

† Calculated from regression line and corrected for percentage of extraction recovery—values corresponding to aldosterone activity over 95% have not been calculated.

‡ Not estimated.

The activity shown by the extracts was quite independent of the total twenty-four-hour volume of urine (table II), this fact confirming the observation reported by Luetscher and Johnson (1954).

It was also found that the urinary Na^+/K^+ ratio in patients before operation was greater than 1, but that after operation it was very much less than 1. If the values obtained in the bio-assay and the Na^+/K^+ ratio of the patient's urine are plotted in the same graph (fig. 2), the diagrams which result show remarkable similarity. Great importance is attached to this fact because the activity of the extract in the course of the bio-assay is assessed also in terms of Na^+/K^+ variation. The fact that an observation (Na^+/K^+ ratio in urine of the patient) made by a non-biological method correlates so well with the results of the bio-assay seems strongly to point to a relationship between both variables.

Discussion

Previous Clinical Data

That the adrenal cortex might play an important rôle in the disturbances of electrolytes following surgical trauma had been suggested earlier by Pearson and Eliel (1949), Elkinton and Tarail (1950), and Mach (1954).

An important contribution has been made by Moore and Ball (1952), who made several attempts to reproduce under experimental conditions in man the metabolic changes which appear after operation. A mock operation with perfect reproduction of operative diet, management and ambulation, and with intentional lack of fear, pain, anæsthesia, tissue trauma, and adrenal discharge was carried out, with the result that among biochemical features the nitrogen metabolism resembled the postoperative pattern, but there was a lack of a sharp K^+ loss in the first day following operation.' On the other hand, a Na^+ loss was present instead of the well-known feature of Na^+ retention. When corticotrophin was given to reproduce the postoperative manifestations Moore and Ball observed the dose used here produced somewhat more 11-17-oxysteroid activity on the third and fourth postoperative day and less desoxy-like (salt conservation) on the first day. That corticotrophin does not increase aldosterone in the urine has also been shown by Cope and Llaurado (1954), Luetscher and Johnson (1954), and Venning et al. (1954).

A valuable and clear approach was made by Le Quesne (1953), who subdivided the manifest Na^+ retention after operation into two episodes called early sodium retention and late sodium retention, the former being specifically accompanied by acute K^+ excretion. Le Quesne pointed out that these two phenomena can be explained by a release of two different hormones from the adrenal cortex, each of which causes retention of Na^+. Moore (1953) has also indicated the possibility of a dissociation between activity like that of Compounds E and F and deoxycortone-like (salt-retaining) activity.

Previous Biochemical Data

Several investigators had previously shown that there is an increased excretion of cortico-adrenal steroids after operation, but hitherto no evidence of salt-conserving activity in the urine of postoperative patients had been reported. Weil and Browne (1939, 1940) reported as a result of their experiments using the cold-exposure test described by Selye and Schenker (1938) that urine of postoperative patients possesses material capable of protecting adrenalectomised rats against cold. Dorfman et al. (1942) found also by the cold-exposure test increased adrenocortical material in extracts of urine of postoperative male patients. Venning et al. (1943, 1944) found in human postoperative urine substances able to protect adrenalectomised rats against lethal action of low temperatures, to maintain life and growth of adrenalectomised rats, and to induce deposition of glycogen in the livers of fasted adrenalectomised rats. Cope and Hurlock (1954) found by paper chromatography for separating steroids that an operation such as gastrectomy causes a sharp rise of corticosteroids for several days. F

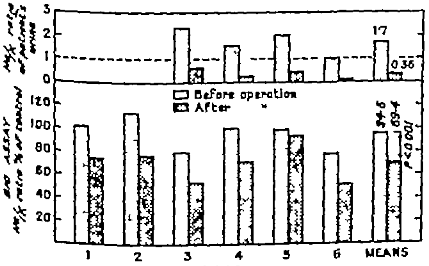

Fig. 2.—Upper scale, Na+/K+ ratio of patient's urine before and after operation; lower scale aldosterone activity of human urine before and after operation. Note correlation between scales.

1954), by estimating the level of 17 hydroxycorticoids in the blood, have also shown that there is a large increase of them after surgery

Although all these reports confirm the increased production and excretion of steroid materials after operation, it must be admitted that aldosterone by itself is not responsible for all these findings Despite the remarkable biological activity of the urine of patients after operation, the average excretion in terms of aldosterone in the twenty-four hours following operation is only 1 11 μg, a quantity so minute in comparison with the postoperative daily total steroid output of 6 3 mg (Cope and Hurlock 1954) that it is not surprising that variations in aldosterone excretion cannot yet be determined by chemical methods Thus Mach et al (1954) and Prunty et al (1954) have observed that there was no increase in the excretion of 17-ketosteroids or of 11-17-hydroxycorticoids when aldosterone in a dosage of 100–1050 μg daily was given to several patients It is for this reason that resort must be had to bio assay

To sum up, it can be concluded that, although several previous workers have shown increased activity of the adrenal cortex after surgical trauma, this activity was almost certainly due to 11-17-oxycorticoids, and hitherto there has been no evidence of changes of excretion of " salt conserving " hormone after operation The results of the present experiments prove conclusively that a " sodium retaining " factor is excreted immediately after operation simultaneously with a large loss of K^+ and an inversion of the urinary Na^+/K^+ ratio Since aldosterone has been chromatographically isolated (Cope and Llaurado 1954, Luetscher and Johnson 1954, Luetscher et al 1954) in the urine of patients having similar disturbances in electrolyte excretion, it appears highly probable that the factor in question is aldosterone Moreover increased excretion of this hormone after operation explains satisfactorily the sudden sharp inversion of electrolyte excretion forming part of the normal pattern of metabolic response to surgery

Although Moore (1953) cautiously stated that increased excretion of corticoids after operation does not necessarily mean overproduction of them, since this increased elimination might be due to alterations in the liver metabolism of, or in the kidney threshold for, steroids, this appears unlikely for the following reasons

(1) Prunty et al (1954) have recovered aldosterone from human urine after its administration

(2) The increased postoperative excretion of aldosterone accompanies the changes that theoretically would be expected from overproduction of this hormone, according to its biological activity—i e, sharp K^+ excretion and sudden Na^+ retention The administration of aldosterone reproduces the same pattern of electrolyte response (Na^+ retention and acute K^+ excretion) as after operation (Mach et al 1954, Kekwick and Pawan 1954)

(3) There is a remarkable chronological relationship between the onset of the aldosterone effect and the metabolic changes following surgery, as reported independently Mach et al (1954), on the one hand, showed that the influence of aldosterone on electrolyte excretion is evident three to six hours after injection, and, on the other hand, it is well known from the earlier work of Blixenkrône Møller (1940) that the sharp K^+ excretion following surgery begins within 6 hours after operation

(4) The amount of aldosterone excreted bears no relation to the 24 hour volume of urine If the cause of increased aldosterone excretion lay in the kidney, one would expect to find a relation between the total output of urine and the excretion of aldosterone, but there is none

(5) Franksson and Gemzell (1953) and Franksson et al (1954) have shown that there is a large increase of adrenocorticoids in the blood before the increased excretion in urine shown by other workers This may be taken as indirect evidence that a high output of aldosterone in the urine indicates a high concentration of this hormone in the blood

The detailed clinical observations of Moore and Ball (1952), Le Quesne (1953), and Moore (1953) have laid down the foundations for a thorough investigation b bio assay of the adrenocorticoids participating in th metabolic response to surgery Further research is sti needed to elucidate the factor or factors responsible fo " late sodium retention," to define the clinical impl cations, and to interpret the increased excretion aldosterone immediately following surgery Anoth promising field for investigation is the establishment the factors or substances stimulating or governing th production of aldosterone, since corticotrophin is not specific stimulus Selye (1950) suggested that the somat tropic hormone might be a specific stimulant of " mine alo corticoids," and Venning et al (1954) have reporte that, after administration of growth hormone, there an increase in the Na^+-retaining factor present in th urine of normal individuals If this finding is confirme by other workers, this relationship between aldosteron and growth hormone would be extremely interesting

In accordance with the new known facts about th regulation of electrolytes by the adrenal cortex it seen adequate to suggest that the terms " deoxycortone lik activity" and "mineralo corticoids" should be abandone and the more *logical* and *precise* " *aldosterone lik* activity " and " aldosterone-like corticoids " substitute

Apart from speculations it can be concluded that, wha ever steroids may be involved in the late sodium retentio the sharp loss of K^+ following surgery is associated wi *increased production of an electrolyte controlling adren* corticoid, which there is good reason to believe is ald sterone, and that overproduction of this steroid form part of the normal pattern of metabolic response surgery

Summary

By a bio assay designed to detect aldosterone it h been shown that a sodium retaining and potassiu excreting factor is present in the urine of patients aft surgical operations

Some patients excrete this factor before operation, b in all cases the excretion after operation is very muc greater than before operation

Evidence is adduced that this activity is due to ald sterone, the recently discovered electrolyte regulati cortico-adrenal hormone

The increased excretion of electrolyte regulati corticoid is shown to accompany the sharp potassiu loss and the early sodium retention which are comm features of the normal response to surgery Excreti levels of this corticoid correlate qualitatively with th Na^+/K^+ ratio in the urine of patients before and aft operation

Increased production of the electrolyte regulati corticoid may be one of the factors responsible for th electrolyte changes in the immediate postoperative perio

The results of assays with pure crystalline aldosteron are also reported This steroid is 100 times as strong deoxycortone when assayed in terms of Na^+/K^+ urinar deviation in the rat by the present method

I wish to thank Prof M F A. Woodruff and Dr C L Cop for their encouragement in this investigation and for criticis of the manuscript, Prof T Reichstein, of Basle, for a gi of pure crystalline aldosterone, and Mr G Spears fo assistance with the statistical analysis

A POSITIVE-NEGATIVE PRESSURE RESPIRATOR

G T SMITH CLARKE
M.I.Mech.E., F R.Ae.S
CHAIRMAN OF THE HOSPITAL MANAGEMENT COMMITTEE GROUP 20 BIRMINGHAM REGIONAL HOSPITAL BOARD

J F GALPINE
M D Leeds M.R C P.E., D.P.H D C H
MEDICAL SUPERINTENDENT WHITLEY HOSPITAL, COVENTRY WARWICKSHIRE

ARTIFICIAL respiration by intermittent positive pressure (I.P.P.) may contribute to the development of shock by lowering cardiac output (Astrup et al 1954) This is principally due to interference with venous return to the heart by raising the mean intrathoracic pressure Maloney and Whittenberger (1951a) say that I P P does not obstruct blood flow through the pulmonary capillary bed any more than does a normal inspiration producing the same degree of inflation In normal people receiving I.P.P the venous gradient is rapidly re established by a rise of systemic venous pressure but this may not happen if the vasomotor responses are compromised (Maloney et al. 1953)

To avoid this danger in I P P a method of giving adequate ventilation at an intrathoracic mean pressure approximating to atmospheric or even less is needed and this is possible by using negative pressure in expiration—i.e., positive negative pressure (P N P) Without the use of negative pressure the mean pressure in I P.P can be minimised by making inspiration as rapid as is consistent with satisfactory ventilation and by ensuring all possible freedom of expiration to allow a maximum of time for a pause after expiration at zero (i e atmospheric) level Apart from considerations of this sort Maloney et al (1953) state that the shape of the pressure curve is of little significance The use of negative pressure does not seem to have any direct effect on the rate of emptying of the lungs (Asmussen 1955) Fear of using negative airway pressure—especially of causing pulmonary œdema is considered groundless by Maloney and Handford (1954)

Certain pressure respirators are fitted with negative pressure devices on the Venturi principle Price et al (1954) studying some commercially available respirators speak of the high resistance in Venturi devices but found that a manually operated P N P apparatus with a negative pressure reservoir of large volume was capable of ventilating adequately at zero or negative mean mask pressure After testing a respirator having a Venturi attachment we concluded that the latter was largely ineffective probably because of swamping by the volume of positive pressure in the oncoming wave of expired air In these circumstances a Venturi becomes a potential obstacle owing to its narrow aperture In the new respirator the use of a pump ensures an adequate volume of negative pressure

An interesting comparison has been made by Maloney and Whittenberger (1951b) who consider that alternating negative and positive pressure applied to the body in a tank respirator are the physiological equivalents respectively of positive and negative pressure applied to the airways by a P N.P respirator

The usual type of pressure operated inspiratory-expiratory valve (P O valve) used with an I P P pump does not work satisfactorily with a negative pressure phase and the best solution of this is a mechanically operated inspiratory-expiratory valve (M. valve) as in the present machine This also abolishes any risk that the valve will stick as may happen with a P O valve A M valve offers negligible resistance to expiration if accurately timed and will never vary In contrast to this a P O valve must by definition have a resistance and is an inevitable (if small) obstacle to expiration It will moreover open later in the cycle if the build up of expiratory pressure is slowed by another resistance thus tending to magnify the effect of for example a small calibre endotracheal tube Thus a M valve offers definite advantages at any rate if for use over long periods and in conjunction with a P N P machine

The prototype respirator described below was wholly designed and constructed by one of us (G T S C)

Description of Machine

This respirator is designed to provide either P N P or I P P and to be reliable and efficient in both The construction is simple and robust, and any person of average ability can learn from the instruction plate (to be fitted to each machine) all that is necessary for efficient use and maintenance Apart from the driving motor and its switch no electronic apparatus is used There is no interference with radio or television when the machine is working It is essentially a hospital rather than a research apparatus

The machine is built as a complete unit (fig 1) It is mounted on castors and arranged in two tiers, the upper comprising the pumps, controls, driving motor, gearboxes, M valve, and mechanism for manual operation In an emergency the handle provided can be fitted on to the splined shaft at the front of the machine, it must be turned steadily at the required rate in the direction shown by the arrow The lower tier carries the humidifier, negative pressure vessel, and dry spirometer, and provides parking space for the handle for hand operation The apparatus is of suitable height to stand alongside a standard hospital bed

In addition to the motor switch, a "mains on" indicator, and a compound pressure gauge, there are four controls on the top of the cabinet

(1) The front transverse lever varies the stroke of the positive pressure pump and controls the volume of air (or air oxygen mixture) delivered It is calibrated in 15 stages from 200 c cm to 1500 c cm , representing air at atmospheric pressure pumped to the valve box at each stroke The minimal volume has been reduced to cater for the needs of children A dead weight safety valve is provided to blow off at a pressure of 30 cm water

(2) The lever on the left controls the "dog clutch" in the driving mechanism This has two positions the forward for emergency manual operation, and the rear for normal motor drive

(3) The central lever to the rear controls the stepless speed variations and gives breathing rates of 10–40 a minute This is calibrated in 10 steps of 3 and can be locked at any of these points This lever must not be moved when the machine is stopped It can be used unlocked if thought necessary to adjust rate to a finer degree as the patient recovers

(4) A circular knob on the right controls negative pressure, which is developed in a separate pump If it is set to minimum (as when using I P.P) negative pressure is zero, and expiration takes place through a disc valve (of negligible resistance) placed on the top of the negative pressure vessel When the control is turned towards maximum (– 20 cm water), the value can be read on the compound gauge, which measures pressures in the valve box

The Mechanical Inspiratory-expiratory Valve

We believe that this is the first mechanical respirator to be fitted with a M valve It is built into the side of the cabinet to reduce the length of tubing needed to reach the endotracheal-tube connection, this arrangement and the very small volume of the valve box keep "dead space" to a minimum The valve mechanism comprises two stainless steel poppet valves (inspiratory and expiratory) working in a housing of hard bronze They are closed by springs and operated by cams as in automobile and aero engines and timed so as not to be open together, however fractionally Modern valves of this type are reliable over long periods even when running at dull red heat and speeds of over 4000 revolutions a minute In the respirator working at room-temperature and at speeds about 15–20 a minute they should work indefinitely with minimal attention

The valve cams are designed to give a breathing pattern of inspiration 1, expiration 2 Since the inspiration period is 120° compared with a pressure stroke period of 180°, pressure is built up before the inspiratory valve opens This helps to overcome the inertia of the air in the humidifier and tubing and makes possible a "zero" period at the end of expiration when I P.P alone is in use If desired, the connections can be arranged to have the dry spirometer continuously in circuit, this is not detrimental to the breathing pattern if negative pressure is adjusted to compensate for the slight additional resistance to expiration

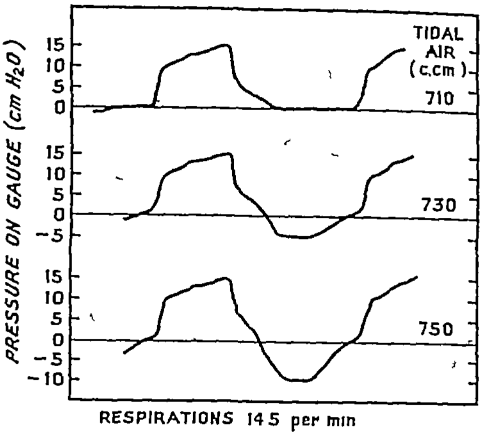

Fig 2—Pressure curves, close to tracheal tube, recorded by Dr Spalding during a clinical test of the respirator

The machine has been thoroughly tested with the aid of an "artificial lung" (Galpine and Smith Clarke 1955) which for this purpose was modified to record a negative as well as a positive pressure/volume curve We are indebted to Dr W Ritchie Russell and Dr J M K Spalding (Oxford), who tested the machine by using it to ventilate a tracheotomised adult female patient continuously for five days (fig 2) Apart from some minor suggestions they considered "the design and performance to be most promising"

FATAL HYPOGLYCÆMIA IN EARLY NON-ICTERIC INFECTIVE HEPATITIS

B E Tomlinson
M B Lond , M.R C P
PATHOLOGIST, GENERAL HOSPITAL, NEWCASTLE UPON TYNE

Hypoglycæmia due to liver disease was originally described by Nadler and Wolfer (1929) in a case of primary liver cell carcinoma Conn (1940, 1947) has reviewed spontaneous hypoglycæmia and described the liver disorders with which it may be associated

Hypoglycæmia in fulminant infective hepatitis is not uncommon Of 178 cases analysed by Lucké and Mallory (1946) a blood sugar level lower than 30 mg per 100 ml was recorded in 16 All these cases, however, showed massive destruction of liver cells, and the clinical diagnosis of severe liver disease was never in doubt

Death in the early stages of infective hepatitis is probably rare In the present case death took place in hypoglycæmic coma after a short illness and before the

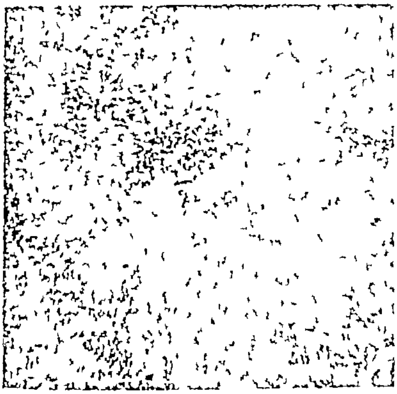

Fig. 1—Liver showing inflammatory infiltration of portal tract. (van Gieson. ×65.)

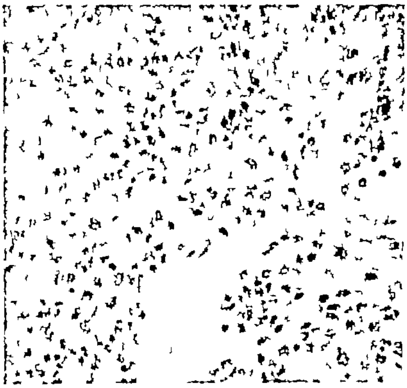

Fig. 2—Portal tract with cellular infiltration and vacuolated peripheral liver cells (Hæmatoxylin and eosin. ×270.)

onset of jaundice and although the liver histology resembled in most respects the findings in early mild infective hepatitis, the diagnosis could not have been made with certainty but for the subsequent development of jaundice in other members of the patient's family

Case-report

A girl, aged 6 years, was well and attending school until Nov 15 1953 when she developed a slight cough. On Nov 19 she had a sudden attack of vomiting and was sick about a dozen times. She vomited throughout the night but remained active and with no disturbance of consciousness. At 7 A.M on Nov 20 she fell asleep She called out several times during the first hour and vomited once but then fell into what her mother regarded as a deep sleep She was possibly unconscious from that time

On admission to hospital at 3 P.M on Nov 20 she was deeply unconscious, and ashy pale and could not be roused She had bitten her tongue Every 30 seconds or so she had a short spasm of generalised twitching Her respirations were slightly irregular and jerky No abnormal physical signs were elicited except that her muscle tone varied from minute to minute Her temperature was 97.4 F pulse rate 102 and blood pressure 108/60 mm Hg Investigations performed immediately showed Hb 13.2 g per 100 ml white cells 22 000 per c.mm serum sodium level 320 mg per 100 ml., serum-chloride level 375 mg per 100 ml, serum potassium level 31 mg per 100 ml alkali reserve 48.7 vol % blood urea level 64 mg per 100 ml and blood sugar level 15 mg per 100 ml Lumbar puncture produced clear cerebrospinal fluid under normal pressure with 6 lymphocytes per c.mm

Death took place within two hours of admission.

Necropsy findings eighteen hours after death were as follows. The *liver* weighed 610 g and was extremely pale Its cut surface showed yellowish grey liver lobules of normal size each accentuated by a narrow peripheral margin of reddish brown tissue The *spleen* was moderately enlarged (80 g) but otherwise showed no abnormality Numerous soft lymph nodes, measuring 0.5–1.5 cm across were present throughout the mesentery of the small intestine The largest node was over the head of the pancreas A few petechial hæmorrhages were present beneath the pleura and in the epicardium at the base of the heart

Histology.—There was a uniform infiltration of the portal tracts of the *liver* with lymphocytes a fair number of mononuclears of reticulo-endothelial type a few plasma cells, and eosinophils. This infiltration involved the periphery of the liver lobules, and in a few places was continuous with the infiltration of neighbouring portal tracts (fig 1) A few small foci of similar cells were scattered in other portions of the

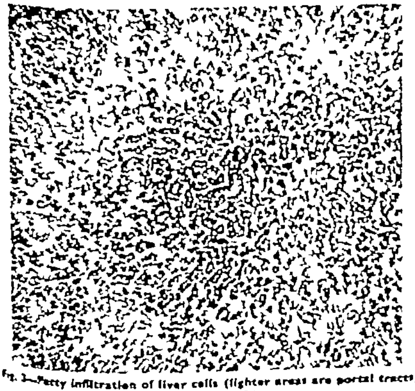

Fig. 3—Fatty infiltration of liver cells (lighter areas are portal tracts) (Sudan IV ×65.)

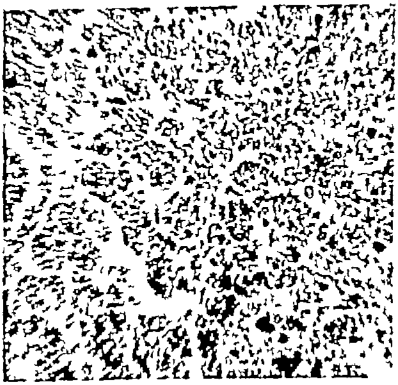

Fig 4—Intense fatty infiltration of liver cells. (Sudan ×270.)

liver lobules The peripheral sinusoids were congested, producing the red rims of the lobules already mentioned The liver cells showed diffuse and very fine vacuolation when stained with hæmatoxylin and eosin, only easily detected at the periphery of the lobules (fig 2) Staining for fat revealed an extreme degree of fine fatty infiltration of all the liver cells (figs 3 and 4), the severity of which was quite unexpected from the appearances of the hæmatoxylin and eosin sections In alcohol fixed material no glycogen was demonstrated *Although all the liver cells appeared equally affected by the* fatty infiltration, the related ischæmia of the centre of the lobules and slight irregularity of the liver cell cords suggested considerable swelling of the central cells and individual cells in other parts No evidence of centrilobular necrosis was found Reticulum stains showed no condensation around the central vein or elsewhere Occasional liver cells scattered throughout the lobules showed an intense eosinophilic degeneration accompanied by shrinking of the cells and rounding of the cell borders The nuclei of such cells were small and pyknotic A few liver cells in mitosis were seen and an occasional doubly nucleated cell There was diffuse lymphocitic hyperplasia in the mesenteric lymph nodes The large node over the pancreas was œdematous, with dilated sinusoids which had prominent lining cells and contained polymorphs and plasma cells The *spleen* was congested, with enlarged germinal centres, some showing cellular degeneration Many sinusoids contained considerable numbers of polymorphs The *kidneys* were congested, and there was a fairly well marked fine fatty infiltration of the proximal convoluted tubules, *with a few foci of necrosis in these tubules and the thick loops* of Henle

Subsequent Family History

Several days after this child's death her sister, aged 5 years, had a slight illness with vomiting, and a fortnight later she became jaundiced for several days, after which she rapidly recovered Five weeks later the dead child's twin brother became jaundiced but was only slightly ill. A few days later the mother became jaundiced, but again the illness was mild and of short duration The illness of the second twin was witnessed by the general practitioner who diagnosed infective hepatitis

Discussion

That the liver lesion was due to infective hepatitis is probable histologically and virtually certain in view of the subsequent family history

The liver changes in infective hepatitis have been extensively investigated since the publication of the aspiration biopsy studies of Roholm and Iversen (1939) Fatal cases show at necropsy almost complete destruction of liver cells (Lucké 1944, Lucké and Mallory 1946), and in many non fatal infections necrosis, particularly centrilobular, is well marked (Dible et al 1943) In the mildest instances, however, this rather characteristic centrilobular necrosis may be entirely absent, and the cellular degeneration limited to solitary cells showing distinctive eosinophilic change at any point in the lobule (Mallory 1947, Keller et al 1951) Lobular disarray, due to swelling and shrinking of liver cells, and evidence of regeneration of liver cells (mitotic figures and multinucleated cells) are often seen Bile thrombi are usually absent in the preicteric phase Even the mildest cases show severe portal infiltration, mostly with lymphocytes, reticulo endothelial cells, plasma cells, and eosinophils

The histological appearances of the liver in the present case are therefore, except for the fatty infiltration, identical with the changes found in mild infective hepatitis, as are also the lesions in the spleen, lymph-nodes, and kidneys

Fatty infiltration of the liver is unusual in infective hepatitis, particularly in the early stages (Weinbren 1952) Its severity and death in hypoglycæmia in the present case initially raised the question of poisoning, particularly by phosphorus or by mushrooms Detailed inquiries revealed no likely source of accidental consumption of any known liver toxin, and all the meals for several weeks had been taken by the rest of the family, *with the patient's twin eating identical food*

The possibility that the fatty liver and hypoglycæmia resulted from malnutrition, with or without an ingested toxic agent, and that the illness was similar to the fatty liver disease which occurs in the British West Indies (Waterlow 1948) did not bear examination The child was well nourished, as were the rest of the family, had no dietetic idiosyncrasies, and, apart from fairly frequent colds, was normal and healthy The illness did, however, resemble very strikingly the rapidly fatal form of "vomiting sickness" (Chambers 1953, Jelliffe and Stuart 1954), some cases of which terminate in hypoglycæmia

No explanation is available for the extensive fatty infiltration in the present case Death took place too rapidly for it to have been the result of the severe vomiting The appearances could result from infective hepatitis developing in a liver already the site of severe fatty infiltration To support this there would need to be evidence of some other factor likely to produce fatty infiltration No such evidence was found clinically or at necropsy That the fatty infiltration could be an unusual response of the liver to a mild attack of infective hepatitis cannot be denied but seems unlikely in the absence of even minor degrees of fatty change in the average case It seems rather more possible that the extensive fatty infiltration was a prenecrotic change in a severe hepatitis in which the development of extensive necrosis was forestalled by death in hypoglycæmia. This is pure speculation, for we have no knowledge of the early changes in the fulminant cases, and the development of necrosis and autolysis eliminates the possibility of demonstrating any pre-existing fatty infiltration

This child died before intravenous therapy could be started, and it is impossible to know whether the coma was reversible Jelliffe and Stuart (1954) record recovery from hypoglycæmic coma of short duration in vomiting sickness, but two patients who were in coma for more than seven hours died despite intensive therapy Treatment in such cases is obviously a matter of the greatest urgency, and only by keeping hypoglycæmia in mind as an occasional cause of sudden coma will any chance of recovery be possible

Summary

Fatal hypoglycæmia developed in the preicteric stage of infective hepatitis, being presumably related to severe fatty infiltration of the liver, a most unusual finding in this disease

Possibly this fatty infiltration represents a prenecrotic change in the liver cells in a case which otherwise presented the histological features of a mild hepatitis

I wish to thank Dr G Davison for permission to publish, Dr J Miller, the general practitioner, and Mr A Hall for the microphotographs

NUTRITION AND FLUID AND ELECTROLYTE BALANCE DURING TREATMENT OF TETANUS

G WILSON
M B Leeds, F R C S
REGISTRAR IN GENITO-URINARY SURGERY THE GENERAL INFIRMARY AND ST JAMES'S HOSPITAL LEEDS

A. D CARE
M A Camb Ph.D Leeds
RESEARCH FELLOW IN UROLOGY IN THE UNIVERSITY OF LEEDS

A BOY aged 15 was admitted with a severe degree of tetanus and kept unconscious for fourteen days with nitrous oxide administered through a tracheotomy tube Convulsions were controlled with a continuous intravenous infusion of suxamethonium chloride (J L Ablett 1954 personal communication)

It was thought that the anæsthesia might have to be continued for three weeks, and that therefore artificial feeding and a fairly strict check on fluid and electrolyte balance would be necessary Few details of nutrition and of the administration of fluids in such cases have been published (Forrester 1954 Honey et al 1954, Lassen et al 1954, Shackleton 1954) The need for adequate nourishment is obvious but careful control of the fluid and electrolyte balance is of paramount importance because the control of convulsions with a continuous infusion of suxamethonium chloride may necessitate the intravenous administration of several litres of fluid daily

Nutrition

No details of the patient's height and weight had been recorded, but it was estimated that his basal metabolic requirements would be about 1500 calories per 24 hr because he was to be kept at complete rest by the administration of relaxants About 900 ml of the following concentrated gruel was given, by stomach tube in four divided doses a day, the tube being removed after each feed

1½ pints of fresh milk 2 eggs 4 oz glucose 1 oz Casilan 2 oz dried milk 1 teaspoonful Marmite 1 tablet (100 mg) ascorbic acid ½ teaspoonful salt	Carbohydrate 208 g Protein 87 g Fat 60 g

The total calorific value was about 1500 calories and the electrolyte content was as follows

Sodium	123·0 m.eq per litre
Potassium	52·4
Chloride	134·0
Calcium	100·0 „

The concentrated feed together with the intravenous fluids administered (see below), gave the patient a daily intake of 1800–2100 calories

No regurgitation developed but with this complication in mind, the provision of more frequent and smaller feeds and the intravenous administration of 20% glucose were considered as alternatives to the routine adopted

Fluid and Electrolytes

Since the water content of the concentrated stomach feed was less than 1 litre intravenous fluids were given to supplement this In calculating the amount of fluid required the following factors were taken into account: (1) insensible losses via skin and lungs (about 1000 ml per 24 hr) (2) output of urine (1000 ml) and (3) excessive losses due to anæsthesia artificial respiration, and sweating which was at times profuse

It was decided that the fluid to be administered should contain sufficient electrolytes to cover normal losses and should be so composed that if the anæsthetist wished an extra 1–2 litres of fluid could be given without danger of overhydration

The solution chosen for intravenous infusion was Howarth's (1954) solution C

Glucose	33 g	approx. 135 calories	
NaCl	3 g	51·3 m eq of Na	+ 70·3 m eq of Cl
KCl	1 g	13·4 „ K	
CaCl	0·2 g	3·6 „ Ca	
MgCl	0·1 g	2·1 „ Mg	
Aqua ad	1000 ml		

From 2 to 4 litres was administered per 24 hours. Together with the stomach feeds this gave a total fluid intake of 3–5 litres a day On this régime the daily output of urine was 1500–3800 ml

The intravenous fluid was administered through an indwelling polyethylene tube so that the patient could be turned frequently without difficulty No major complication developed from the use of such a tube but minor accidents necessitated a change in the site of the drip on three occasions

Collection of Urine Specimens

The patient developed an automatic bladder which emptied whenever he was turned in bed Catheterisation was therefore unnecessary, and little difficulty was experienced in collecting the urine specimens

Discussion

Nutrition

When the patient was weighed about three weeks after admission he scaled 94 lb and ten days later he had increased to 102 lb He had therefore probably lost during his illness well over 14 lb despite what was considered to be a reasonable intake of nourishment which included 87 g of protein

A possible explanation for this loss of weight might be that the patient was in negative nitrogen balance If this were so alternative mechanisms may be postulated:

12	5900	2698	3202	325	216	109	425	259	166	98	80	18	78	23	55

(1) The administration of the anæsthetic, or the disease process per se, may have led to excessive breakdown of protein, possibly brought about by an increase in adreno cortical activity

(2) Prolonged muscular paralysis produced by the administration of relaxants may cause rapid loss of muscle comparable to that which follows denervation

Where there is a substantial breakdown of tissue, however, it is customary to find a concomitant negative potassium balance (Gamble et al 1923), of which there was no evidence in this patient (see below) Nevertheless it is felt that full balance studies would be well worth while in similar cases

Blood Analyses

Throughout twenty days, during which blood analyses were frequently performed, no gross deviation from the normal took place (fig 1) despite the fact that there was profuse sweating from time to time and that, during the transitional period from artificial to natural feeding, the patient had watery diarrhœa lasting three days

Urine Analyses

The results of the daily urine analysis are set out in fig 2 Approximate fluid and electrolyte balances were obtained by correlating total intake and urinary excretion (see table)

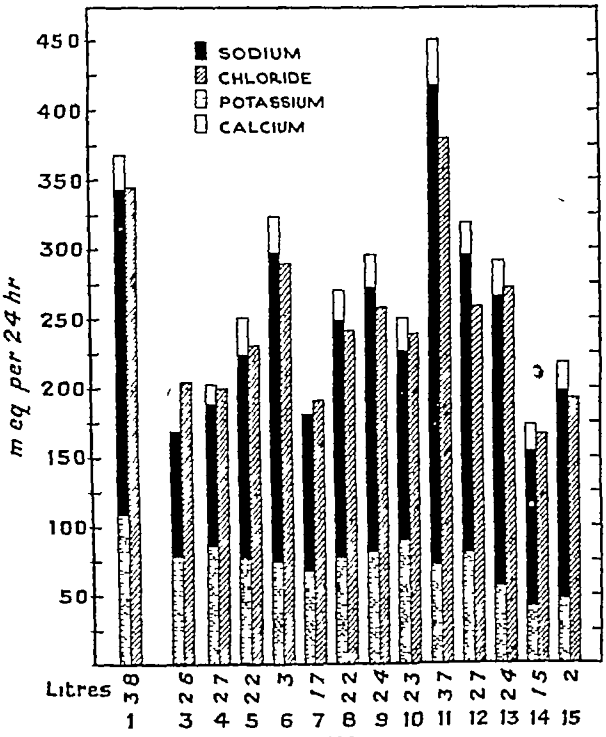

Fig 2—Urine analyses

Since the apparent gains of sodium and chloride ions by the body were in amounts equivalent to one another and, moreover, closely followed the gain of fluid, it was concluded that sweating might have been sufficient to account for this discrepancy An approximate calculation reveals a total apparent gain by the body of sodium chloride of 87 m eq a day This figure could be accounted for not only by the experimental errors involved in collecting the urine but also by the salt lost in the profuse sweating (average composition of sweat 25 m eq of sodium chloride per litre), in the aspiration of bronchial secretion, and in the saliva and fæces (saliva contains 10 m eq of sodium chloride per litre, and fæces contain about 2% of the total intake of sodium [Peters and van Slyke 1932] but no chloride)

In addition to the total salt content of the body, attention must also be paid to any alterations in its total potassium content In the present case the apparent total gain of potassium in the period studied was 80 m eq The potassium content of the fæces in the same period could be taken as 8% of the total intake of potassium (Peters and van Slyke 1932)—i e , 75 m eq Since the plasma potassium level remained normal, the residual 7 m eq of potassium was presumably lost in the saliva and bronchial secretions (saliva contains about 25 m eq of potassium per litre)

The urinary output of calcium was often as much as 26 m eq per 24 hours, but this probably reflects the large intake of calcium and the fact that the patient was totally recumbent The amount of calcium in the fæces was not estimated , hence the exact state of calcium balance was unknown

Summary

The nutrition and fluid and electrolyte balance in a case of tetanus are reported

Blood analyses over twenty days showed no significant deviation from normal

A satisfactory correlation was obtained between the administration and the excretion of fluid and electrolytes

We wish to thank Dr H G Garland for allowing us to investigate his patient , the staff of the department of urology for their technical and secretarial assistance , and Mr J Hainsworth and Miss C E Campbell, of the department of medical photography, St James's Hospital, for the illustrations

LEIOMYOSARCOMA OF THE STOMACH
WITH INTRAPERITONEAL PERFORATION

J F HORLEY
M.B Lond.
PATHOLOGIST ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON, SUSSEX

REPORTS of leiomyosarcoma of the stomach are sufficiently uncommon for individual examples to deserve attention on this account alone Moreover because the prognosis with suitable treatment may be excellent the importance of distinguishing this neoplasm from carcinoma of the stomach makes its recognition especially important

The incidence is difficult to compute accurately for many reports have been concerned with single examples Watson (1950) states that most authorities accept an incidence of 1 case in every 1000 malignant gastric neoplasms. However Marvin and Walters (1948) found in the records of the Mayo Clinic for 1907–47 16 cases among 10 000 surgically verified cases of gastric carcinoma, an incidence of 1 in 625 but 10 of these had occurred in 1940–47 Marshall and Meissner (1950) found 9 cases of leiomyosarcoma in 1171 operations for malignant growths of the stomach and Cowdell (1950) described 5 examples found among 370 gastric neoplasms These figures suggest that the present incidence may be about 1 in every 100 gastric malignant growths

Whatever the true incidence may be its importance can never be judged by weight of numbers alone for if it is recognised there may be a chance of cure in a patient who would be considered hopelessly inoperable had he a gastric carcinoma of similar extent

Case report

A man, aged 40, was admitted to the Royal Sussex County Hospital complaining of severe pain on the left side of the abdomen of sudden onset for the past 6 months he had had discomfort in his epigastrium

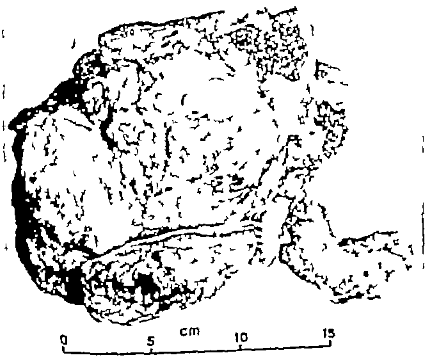
On examination he was restless sweating and in pain with blood pressure 105/70 mm Hg His abdomen was distended and tender with guarding and some rigidity of the left side Bowel sounds were diminished Clinically a perforated viscus was suspected

Laparotomy was done by Mr W R. Forrester Wood A large cystic swelling was found adherent to the stomach and transverse colon and had perforated into the lesser sac It was considered impossible to remove the tumour at that time instead it was incised and drained of some 30 oz of dark fluid The abdomen was closed with drainage of the neoplasm and lesser sac

Postoperatively the hæmoglobin was 92% (100% = 14 8 g) Subsequently in spite of intravenous therapy the blood urea level rose to 178 mg per 100 ml. on the tenth postoperative day and twenty four hours later the patient died

Necropsy twenty four hours later showed no evidence of recent loss of weight In the abdomen was found a tumour with irregular contours but roughly spherical (see figure) and measuring 21 × 16 × 10 cm Its centre had degenerated and been discharged leaving a wall which varied in thickness from 3 cm. to paper thinness and was firm and rubbery in consistence Two perforations of this cystic neoplasm led into the peritoneal cavity one opened into the lesser sac and the other was the aperture through which the tumour had been drained to the surface at operation. The neoplasm was adherent to the transverse colon and the spleen, but the adhesions could be broken down easily It was blended intimately with the tail and body of the pancreas and one segment of the growth formed part of the wall of the stomach A perforation of the gastric mucosa, measuring 2 × 1 cm. opened into the centre of the neoplasm and thus communicated with the two perforations already mentioned All the remaining organs of the body were normal in particular no metastasis was found.

Microscopy—Sections taken from many parts of the neoplasm were stained with hæmatoxylin and eosin Van Gieson, phosphotungstic acid hæmatoxylin and Mallory's trichrome stains The tumour consisted chiefly of fusiform cells which stained like smooth muscle The morphology and arrangement of the cells varied considerably in different parts of the neoplasm in some there was a very regular pattern of interlacing fibres with few mitotic figures in others the cells were plumper and pleomorphic with 2–3 mitotic figures per high power field The tumour had broken through the muscularis mucosa of the gastric wall and was nowhere completely encapsulated It was growing well into the substance of the pancreas but except in a few places the growing edge was tipped with a layer of fibroblasts and round cells The appearances were those of a leiomyosarcoma of the stomach



Leiomyosarcoma of stomach: complete specimen. Tail of pancreas can be seen emerging from right border Uppermost perforation led into lesser sac.

Discussion

Leiomyosarcoma of the stomach is described as endogastric when the main bulk of the tumour usually sessile lies within the lumen of the stomach and exogastric when it expands outside it According to Golden and Stout (1941) these tumours occur with equal frequency in either sex and may be found at any age

To the naked eye the tumours are usually irregularly lobulated and to the touch they are firm and rubbery quite unlike stony hard and friable carcinoma Pedunculation with cyst formation from central degeneration of the neoplasm is not uncommon in the exogastric type Extension of growth takes place by slow expansion and the tumour's invasive powers are usually slight hence metastases are slow to develop and were seen in less than 20% of the reported examples However a few cases such as that of Lyons and Schneider (1943) have been described in which widespread metastases were found in the presence of a relatively small primary growth

Microscopically, increased mitotic activity and invasion of neighbouring organs may be found but parts of the tumour especially in isolation may be difficult to distinguish from simple leiomyomas. For this reason and because the term leiomyosarcoma although histologically correct may suggest erroneously a highly malignant neoplasm Golden and Stout (1941) prefer to describe them as malignant leiomyomas.

Clinically, leiomyosarcoma of the stomach especially the exogastric type may be completely silent until some complication arises Intestinal blood loss from ulceration of the overlying gastric mucosa may lead to severe and progressive anæmia and this combined with the paradoxical coupling of a large epigastric tumour with slight loss of weight may enable the diagnosis to be made preoperatively

The present case is unusual in several ways Anæmia was not a feature and the tumour although large was not palpable possibly because of cystic degeneration

Perforation into the peritoneal cavity, causing an acute abdominal emergency, has been reported previously only 5 times in 4 (Fritzsche 1918, Baumgartner 1939, Mass and Kirshbaum 1940, Golden and Stout 1941) it was fatal, but in 1 (Shepherd 1950) resection was followed by recovery In 3 of these 5 cases the tumour was mistaken before necropsy for a perforated gastric carcinoma

Summary

A case of leiomyosarcoma of the stomach with perforation into the peritoneal cavity is described

Leiomyosarcoma of the stomach is diagnosed more often nowadays and may not be so uncommon as used to be supposed

Such cases repay diagnosis because the prognosis is good after surgical excision

I wish to thank Mr Forrester Wood for allowing me to report a case admitted under his care and for the interest he has shown in the preparation of this paper

LEIOMYOMA OF THE STOMACH

AN UNUSUAL CASE

H R Ker
M B Lond, F.R C S
SURGICAL REGISTRAR, CHARING CROSS HOSPITAL GROUP,
WEMBLEY HOSPITAL

Myoma of the stomach is not an exceptionally rare tumour Aird (1949) states that it occurs once in every 2000 gastric neoplasms It may be pedunculated and attached to the serous or mucous aspects of the stomach, and usually presents by causing pyloric obstruction or ulceration of a submucous growth The case here described is of interest because the only symptom was nocturnal dyspepsia, present for some years, and because of the unusual manner in which it finally became an emergency

Case-report

The patient was a fit retired Guards' officer of 77 On Feb 18, 1955, he slipped and fell on ice, and was brought to Wembley Hospital complaining of pain in the left hip Clinical and radiological examination showed an intracapsular fracture of the neck of the left femur, and he was admitted for pinning

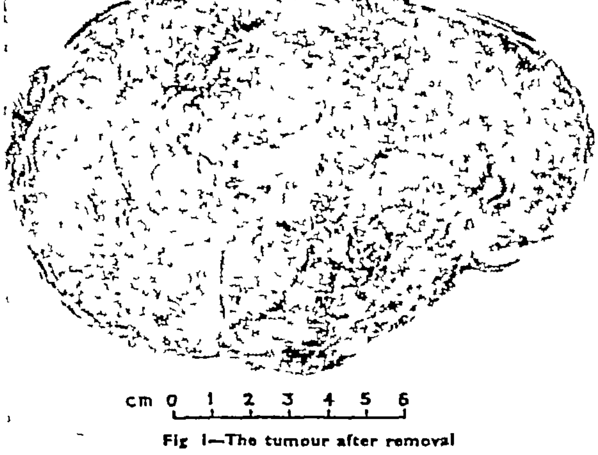

Fig 1—The tumour after removal

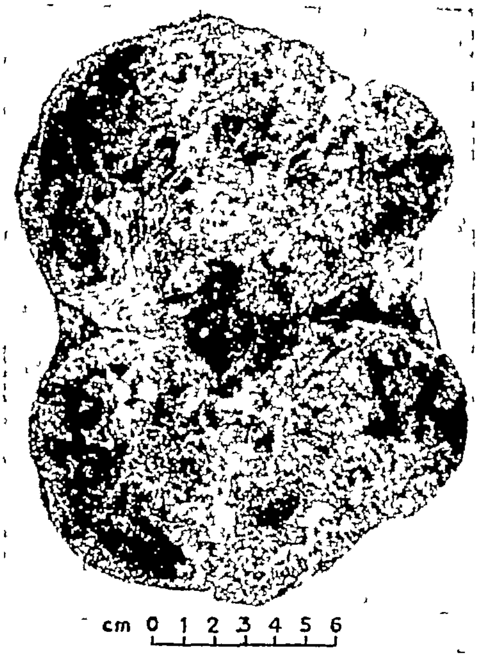

Fig 2—The cut surface of the tumour

In the course of routine preoperative examination he stated that he was perfectly well except for nocturnal dyspepsia, from which he had suffered for about seven years There was a slight feeling of fullness after meals during the day, but when he retired to bed he would get colicky epigastric pain, and would vomit a small amount of bile stained fluid almost every night The house surgeon discovered a round, mobile, non tender tumour, the size of a grapefruit, situated in the epigastrium just to the right of the midline The only other abnormality was a hydrocele of the right tunica vaginalis

It was felt that the treatment of his fracture was of more urgent importance than his abdominal tumour, and as X-ray examination did not reveal any evidence of a secondary deposit, a Smith Petersen pin was inserted by Mr A J Cokkinis on Feb 24

Postoperative progress was satisfactory, apart from his old feeling of epigastric discomfort, and bilious regurgitation on the first day On Feb 26 he complained of more pain, and the vomiting became more severe A milk drip was tried, but this did not relieve him, and an intravenous drip with gastric aspiration was set up

I first saw him on the 4th postoperative day, by which time he had been on intravenous fluids for three days He had been taking fluids by mouth, but the aspirations had exceeded the intake by about 3 oz per day He was a thin man, with a hard round mobile tumour in the epigastrium to the left of the midline This fact was pointed out to the houseman, who announced himself to be undismayed—the tumour had been on the right on admission, and if it chose to move, he could not hold himself responsible for it At this stage it was found that a barium meal performed at the request of his own doctor in 1949 was available This showed that the stomach and first part of the duodenum were pushed to the left apparently by some radiotranslucent body These films had been taken with the patient standing There had apparently been no clinical evidence of a tumour at that time

It was decided that since gastric obstruction was complete, laparotomy must be performed The provisional diagnosis was carcinoma of the stomach, or pancreatic cyst

Operation

On March 1, after anæsthesia had been induced by Dr R J Clausen, the abdomen was palpated, and the tumour could not be felt at all in the epigastrium The abdomen was opened through a left paramedian incision A large tumour 15 cm. by 12 cm (figs 1 and 2) was found in front of the descending colon just below the level of the umbilicus When it was delivered into the wound, it was found to be attached to the centre of the lesser curvature of the stomach by a pedicle three fingers breadth across, in which were running large blood vessels. The tumour by moving to the left had caused a partial volvulus of the stomach. There were no secondary deposits, and no other cause of intestinal obstruction could be found.

The pedicle was ligatured in three bites, the tumour removed, the raw area buried in peritoneum, and the abdomen closed.

Postoperatively, the patient's condition improved rapidly. The Ryle tube was removed on the following day and he resumed a full diet on the fourth postoperative day. [illegible] the rest of the stay in hospital necessitated by his fractured femur, he suffered no dyspepsia, either lying or standing. When seen in outpatients two months later he stated that his old pain and vomiting had completely gone. The microscopic section of the tumour showed a typical myoma with no evidence of malignancy.

Discussion

It seems, from the history, the size of the tumour and the previous barium meal, that this tumour had been present for at least seven years. It apparently caused little trouble when the patient was standing upright, but when he lay down at night, it slipped to the left, falling into the hollow at the side of the lumbar vertebral bodies, causing a partial volvulus of the stomach and his pain and vomiting. This was well seen when the patient was relaxed under anæsthesia and the tumour then descended even further on the left and could not be felt in the epigastrium. When he took to his bed after the pinning of his femur, the tumour was unable to return to its normal position and obstruction became complete.

I wish to thank Mr A J Cokkinis for his permission to report this case.

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION AND SOCIETE FRANCAISE D'ORTHOPEDIE ET DE TRAUMATOLOGIE

On May 5–7 the association and the society held a combined meeting in Paris under the chairmanship of their presidents, Prof Bryan McFarland and Prof P Padovani.

Surgery of the Paralysed Lower Limb

Equalisation of Length

Mr R I Stirling (Edinburgh) said that when shortening of the longer limb was indicated he preferred, in the case of the femur, a long oblique osteotomy of the mid-shaft fixed by transverse screws after the necessary overlap. Union was certain, which it was not after transverse resections, and he disliked the subtrochanteric operations because of possible damage to the blood supply of the epiphyseal region and later osteo-arthritis. Stapling of the epiphyses was uncertain and in any case would not provide more than an inch of shortening. In the tibia he used a Z resection. $1^1/_2$ inches of shortening was the limit acceptable at one operation, but it could be repeated later. The calf muscles were sometimes slow to recover, and a raised heel for a while was helpful.

In bone-lengthening operations the counter pressure points should be in the bone itself and not beyond a joint for fear of overstretching the ligaments. Equally one must beware of damaging a joint surface by undue pressure. He used four pins in the same bone, and in the case of the femur took care to distract the knee first. He used a Z-osteotomy in both femur and tibia and emphasised the importance of complete division of periosteum and fascia. In the case of the tibia there was grave danger that the lower end of the fibula might lag behind, rendering the ankle joint unstable, and he therefore preferred now to fuse the lower end of the fibula diaphysis to that of the tibia, particularly if the lower end of the fibula already lay unduly high.

A poor circulation already present in the limb was no contraindication to bone lengthening. The best age was 11–13, but it could be done earlier if the difference in length was not altering [illegible] in a completely flail limb. Over the age of 16 union was much slower to occur. In cases of partial paralysis bone-lengthening operations often altered the muscle balance, so that they should precede any stabilisation or tendon transplant operations. If the muscles were already balanced it was usually better to shorten the other limb.

In 120 cases he had had only 4 of interference with the peripheral circulation and all recovered; the increase should not exceed $^1/_{16}$ inch per day. The incidence of subsequent arthritis had not been significant, and any distortion of the foot was usually easily corrected by manipulation.

Paralytic Lesion of the Hip with Particular Reference to Dislocation

G Blundell Jones (Exeter) remarked that the inherent stability of the hip could be spoilt by the presence of contractures or by alterations of the bony contours. Paralysis led to coxa valga, and coxa valga was a potent cause of dislocation. Pelvic obliquity might be due to contractures of either hip or trunk. With regard to corrective procedures he thought that it was probably impossible by tendon transplant to replace the hip abductors. Mustard's iliopsoas transplant was the most effective method. Osteotomy of the base of the femoral neck fixed with a Capener plate was very satisfactory for marked coxa valga, and not only in paralytic cases. In spastic cases preliminary tenotomies and occasionally shortening of the femoral shaft might be required. He remarked that the onset of paralysis after the age of 2 might lead to coxa valga but rarely to dislocation; dislocation was almost always the result of poliomyelitis in infancy. Shelf operations or arthrodesis were rarely indicated. In planning treatment the degree of coxa valga, rotational deformity, and condition of the acetabulum all needed assessing. If arthrodesis was required he thought the Charnley central dislocation procedure was the best.

Tendon Transposition in the Buttock and Thigh

Mr J M P Clark (Leeds) thought that the revulsion which followed the first enthusiasm with which the work of Robert Jones and Tubby was greeted was now on the wane. It was important to realise that it was impossible to replace a completely paralysed muscle, that no muscle training will ever alter muscle imbalance, and that deformities may recur even after arthrodesis. Tendon transposition was best done to prevent deformity, and transplants needed protection for at least six months after operation.

Replacement of hip abductors was most difficult; the iliopsoas transplant was satisfactory if a normal gluteus maximus and sartorius were present, but it was a severe operation. In the presence of a good gluteus maximus the backward shifting of the origin of tensor fasciæ femoris could help a weak gluteus medius.

In adduction deformity tenotomy, [illegible] and osteotomy all had a place. In preventing [illegible] of the deformity he had successfully tried a [illegible] in which the adductor origin detached from the [illegible] and mobilised with nerve-supply intact was transposed [illegible] femoris and attached to the iliotibial band.

In the case of the knee transference of the quadriceps could be done (1) to prevent [illegible] in a calliper to be discarded, or (3) to prevent [illegible] deformity of the knee. They were most [illegible] the foot was stable and any knee deformity had [illegible] and in the presence of strong hamstrings [illegible] fair plates. [illegible] tendinosus and gracilis [illegible] biceps laterally [illegible] all used, but semimembranosus [illegible] intact. [illegible] stressed the importance of [illegible] coupled action [illegible] hamstrings with the [illegible] the last part [illegible] length movement of [illegible] knee, which [illegible] the big transplant a good [illegible] sartorius and [illegible] effect of this femoris had not been [illegible] reservoir [illegible]

Tendon Transp[illegible] Foot

Mr D M [illegible] said that the [illegible] easy, could [illegible] and did no [illegible] but unfortunately [illegible] a third [illegible] Equinus deformity [illegible] calcaneus [illegible] was [illegible] and [illegible] the [illegible] the big toe region, and instruments were useless in their control.

One must know accurately the power of muscles and what the deforming muscles were—a matter difficult to assess before the age of 5. It was useless to employ as a transplant a muscle whose automatic phase of function was at variance with that of the recipient; hence the futility of transplanting tibialis anterior to the calf. The essential principles were that full passive correction should be possible, the deforming force must be removed, and the paralysed muscle action must be replaced.

Transplants of the peronei to the calf in cases of calcaneo-cavus with or without valgus had failed in more than half of 40 cases. Transplanting extensor hallucis longus to the first metatarsal neck failed in 24 of 39 cases of pronation of the forefoot, and in a similar proportion transposing peronei to the dorsum of the foot failed to improve plano-valgus. The most successful group was that of equinovarus deformities, where only 9 out of 22 failed to give improvement; 6 of the failures were due to the later disinsertion of the transplant from its new attachment. In all groups secondary deformity was not uncommon.

Mr Brooks concluded that despite the many failures tendon transposition was a useful mitigating procedure in carefully selected cases as long as the cause of the original deformity had been eradicated; he doubted whether it was ever worth shifting a muscle which was not itself causing the deformity.

Operations for Relieving Paralysis of Intrinsic Muscles of Toes

Mr T. T. Stamm (London) said that the Lambrinudi procedure of multiple interphalangeal fusions transferred the activity of the flexors from the interphalangeal to the metatarso-phalangeal joints. When the operation was originally designed it was proposed to attack the accompanying cavus deformity six months later, but this had proved unnecessary since successful toe fusions were found to cure the cavus also. For this operation to succeed there must be no fixed deformity of the metatarso-phalangeal joints. Bony fusion must be produced; fibrous ankylosis gave rise to pain. The insertion of axial Kirschner wires produced too many failures of bony fusion; he thought that the best method was to tie the toes down to a Lambrinudi footplate and to leave the splint on for six weeks. The optimum position was slight flexion of the proximal and slight hyperextension of the distal interphalangeal joint.

If there was fixed extension of the metatarso-phalangeal joints, multiple tendon transplants of the long flexors of the toes to the extensors was a better operation, but this was contra-indicated if there was much fixed flexion of the proximal interphalangeal joints. The two procedures were complimentary and should not be looked on simply as alternatives for any given case. Failures were due to choice of the wrong operation, faults in technique, and occasionally absence of bony fusion.

He considered that the operation of transplanting the extensor tendons into the metatarsal necks was a poor one; it was unsound physiologically because the timing of the automatic action of these muscles was wrong for the new function required of them, and in any case the tendons seemed to return by magic to their original insertions.

In the subsequent discussion Mr H. J. Seddon (London) spoke of the need for independent assessment of a surgeon's results from tendon transplants in the foot; the basic idea was good, but fewer cases than were supposed were in reality worth operating on. Prof K. E. Kallio (Helsinki) showed a film of his operation for arthroplasty of the hip, using a cap of skin taken from the abdomen to cover the femoral head.

Osteochondritis of the Hip

Experimental Study

Dr J. Lemoine, working with Dr R. Lagrange, largely at Oxford, had operated on sixty rabbits 2–3 weeks old. Ligation of the anterior circumflex vessels was found to produce only minimal changes, but ligation of the round ligament was followed by varying degrees of enlargement of the femoral head, with flattening, increased radiographic density, and often some subluxation. Angiograms showed increased vascularity of the head. The neck of the femur often thickened and both macroscopically and microscopically the changes were very similar to those seen in Perthes disease.

Perthes Disease

Prof M. Fèvre reviewed a series of cases of Perthes disease: 80% had been in boys; the age ranged from 4 to 13 years, with a maximum between 4 and 7 years. He had not found trauma or infection elsewhere to be important antecedents. Pre-existing coxa valga he had sought but had rarely found. He divided cases into two groups, depending on whether changes started in the top of the femoral head or around the margins of the epiphysis. The former he ascribed to interference with the blood supply from the round ligament, the latter to interference with the supply from the circumflex vessels; primary acetabular change might occur also.

Osteochondritis in Congenital Dislocation of the Hip

Dr P. Petit had observed 23 instances of osteochondritis among 87 congenitally dislocated hips. He had not seen a case occurring on the normal side. The prognosis could not be assessed in the first year of life, and in some of the earliest cases there had been complete disappearance of the head. 10 out of 11 cases under the age of 1 year treated by manipulative reduction and fixation in the Lorenz position were complicated by osteochondritis. He reviewed the possible causes of the condition, and suggested that the important factors were (*a*) forcible reduction; (*b*) too powerful traction (the condition is commoner in high dislocations); and, above all (*c*) pressure on the femoral head associated with poor articular contact and torsion of the capsule and its vessels from fixation in the extreme positions. The younger the patient the greater the danger of osteochondritis; the femoral heads of older patients appeared to be more resistant. All cases were due to therapeutic causes, and he recommended reduction by gradual traction with fixation in not more than 60° of abduction, moderate internal rotation, and about 30° of flexion.

Osteochondritis dissecans

Prof R. Guilleminet (Lyons) described 7 cases of osteochondritis dissecans of the hip (Kœnig's disease). Their ages varied from 12 to 51, with most occurring in the 18–25 age group. 5 were male, 2 female. In most there had been no history of trauma, the onset being gradual over the previous six to eighteen months. A few gave a history of sudden "catching" of the hip, but in most the symptoms and signs were those of an osteo-arthritic hip. He had tried removing the affected area, which was always on the top of the head or slightly medial to it, and had even filled the resultant cavity with bone chips, but the results were poor. If conservative treatment failed, arthrodesis was the operation of choice, though one hip recently treated by arthroplasty was still satisfactory. Histologically the appearances were those of a sequestrum; except over the affected area the articular cartilage of the femoral head was normal. Differential diagnosis involved the exclusion of caisson disease, aseptic necrosis from other causes, and tuberculosis.

DISCUSSION

In the discussion Sir Reginald Watson-Jones (London) emphasised that Perthes "disease" was a disorder from loss of local blood supply due to various causes. Rest in bed for two or three years *could* prevent deformation of the femoral head. One must wait at least twenty years to know whether later degenerative arthritis had in fact been thus avoided, but three years' bed rest in childhood was a small price to pay to avert fifty years of later disability which otherwise followed with such certainty.

Prof J. Trueta (Oxford) illustrated the histological and vascular changes in experimental osteochondritis in the rabbit. There was thickening of the epiphyseal cartilage, and vessels could be seen penetrating vertically into the substance of the femoral head, particularly from the outer side. In the man there was no blood supply to the femoral head from the round ligament at the age of 18 months; almost all came from the outer side. At the age of 4 vessels could first be seen entering the head from the round ligament; only after fusion of the capital epiphysis did anastomosis occur between these vessels and the major supply from the outer side, which also supplied the femoral neck; hence the associated changes in this region. After the age of 16 the anastomosis with circulation from the round ligament was adequate and the danger of Perthes disease past. It had been shown by arteriograms that extreme positions of the hip obstructed the circulation to the femoral head.

Mr A. H. C. Ratliff (Edinburgh) gave the results of a late follow-up on 49 cases of Perthes disease, followed for an average period of 17 years. Apart from a few who received no treatment all had been treated by frame fixation. Assessed by a point system relating to pain, degree of activity, range of movement and radiographic appearances they showed 18 good 19 fair 7 poor and 5 very poor results Although [illegible]5% *of the total were still fully active and free from pain* only 38% had good radiographic appearances. Of the 9 untreated cases only 1 had a good hip The most important factor affecting the prognosis was the state of ossification of the head; the younger the child the better the prognosis The average age of onset of the "good" results was 0 of the "fair" 8 of the "poor" 0 and of the "very poor" 10 *Absence of fragmentation was of good prognostic significance* A good immediate result was likely to be maintained for at least twenty five years, even though half of such cases were unsatisfactory radiographically

Dr O Cassucio (Italy) said he preferred the term [illegible]chondrosis. He had done biopsies of capsule cartilage and bone in 18 cases. These showed fibrosis of the capsule *thickening of the cartilage and the formation of an irregular* layer of vacuolated cartilage deep to it which in places had grown down or herniated into the cancellous bone Islands of cartilage were to be found between necrotic bone trabeculæ—an appearance similar to that seen in other osteochondroses The findings were similar to those found in experimental osteochondritis in rabbits All cultures from the biopsy specimens had proved *negative In confirmation of Japanese* work he had found similar changes to follow experimental wounding of the articular cartilage

Arthroplasty in Late Treatment of Congenital Dislocation of Hip

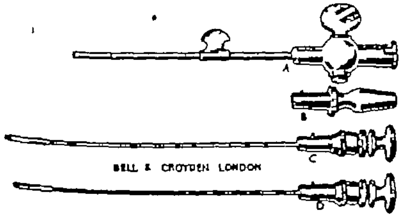
Prof R Merle d'Aubigné (Paris) had done 120 arthroplasties in 90 patients but felt that the indications for any form of arthroplasty should be restricted Arthrodesis was the operation of choice in unilateral cases *only 2 of 17 cases* had been unsatisfactory The Judet operation could give good results but they were too rare In bilateral cases, where *the lesion was asymmetrical* an arthroplasty on the bad side had given poor results in half the cases because of subsequent deterioration in the other hip 12 out of 16 bilateral arthroplasties had been satisfactory Arthrodesis of the more painful side by increasing stability sometimes relieved pain on the other side Resection of the head and neck as in the Girdlestone operation, particularly in those that had had a *previous osteotomy had given very good* results and was also useful where previous arthroplasty with some form of plastic prosthesis had failed After showing *examples of the various groups he concluded by recommending* arthrodesis for the unilateral case and for bilateral cases fusion of the painful side with later arthroplasty or pseudarthrosis on the opposite side if necessary If both sides were stiff and painful at the first examination, then bilateral arthroplasty or resection of head and neck were indicated

New Inventions

ASPIRATION TROCAR AND CANNULA

The disadvantage of the usual trocars and cannulæ used for aspirating fluid from the chest is that, if they are so made as to give a straight run through from cannula via tubing *to syringe* air can enter the pleural space when the trocar is withdrawn and before the aspirating syringe is connected to the cannula. Air may also enter *if attempts have to be made to unblock* the trocar during aspiration Alternatively if the tubing is attached to the trocar by an angled tube obstruction is very apt to develop at the angle and is difficult to overcome during the aspiration

The instrument illustrated here consists of a graduated cannula (11 B.W.G × $2^1/_4$ inches or 14 B.W.G × $2^1/_4$ inches), and a stopcock *with a bayonet* 'Sims' fitting



(A) This connects with a stuffing box and *sharp* trocar (C) a stuffing box and blunt pilot (D) or an adapter (B) attached to a length of rubber tubing which leads to a three-way tap and a *large aspirating* syringe.

With the sharp trocar in position the cannula is inserted into the appropriate intercostal space The trocar is withdrawn To prevent air *entering the stopcock* is closed before the stuffing-box and sharp trocar are disconnected The adapter with the rubber tubing leading to the *three-way tap and aspirating syringe is attached* The stopcock is opened and aspiration is done in the usual way

If the cannula becomes blocked it can be cleared without admitting *air to the pleural space* The stopcock is closed, and the stuffing box and blunt pilot (D) are substituted for the adapter The stopcock is opened and the cannula cleared with the pilot which is then withdrawn The stopcock is again closed while the adapter *is substituted for the stuffing box and blunt pilot* The stopcock is opened and the aspiration continued

These needles are made by Messrs. John Bell & Croyden Wigmore Street London who also supplied the illustration

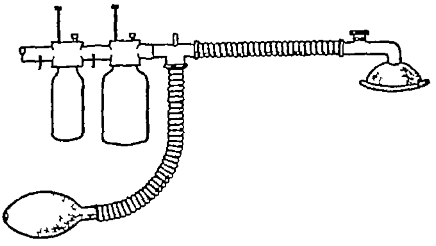
MODIFIED MAGILL'S ATTACHMENT TO BOYLE'S APPARATUS

This modification allows the anæsthetist to hold the *reservoir bag with both hands for artificial respiration*

Many anæsthetists have for years been using circle absorbers with a length of corrugated hosing leading off to the reservoir bag *This method has the great advantage* that the bag may be held in both hands, and much information may be obtained from it. Artificial respiration is more efficient and *less tiring* with two hands than with one hyperventilation is more easily achieved; the anæsthetist is able to circumambulate in a radius of some five feet round the machine to watch the operation attend to drips, and so on

The same facility may be had with the semi-closed circuit as shown in the accompanying figure Magill's



attachment is modified by interposing a standard length of hosing (from a circle absorber) between the bag mount and the bag *The net physical effect of this* modification is to increase the capacity of the reservoir by about 500 c.c. The behaviour of the circuit is virtually unaltered *once filled with gases it is identical with that* of the unmodified attachment

Nitrous oxide/oxygen anæsthesia with moderate artificial hyperventilation *is greatly facilitated by this* modification

Reviews of Books

Clinical Diagnosis

ELMER G WAKEFIELD, B S.A , B SC , M D , F.A.C.P , consulting physician, section of medicine, Mayo Clinic New York Appleton Century-Crofts 1955 Pp 1611 $22 50

IT is rare nowadays to meet a large clinical textbook written by a single author Dr Wakefield has tackled his formidable task with courage and energy, and the thoroughness and skill with which he has carried it out are no less remarkable Single authorship gives unity and balance to the contents and style of a book, and it averts repetition—virtues which are seldom evident when there are many contributors and one hard-pressed editor The increasing complexity of medicine has made the single author's task very difficult—but, as this book shows, not impossible It is a considerable tribute to Dr Wakefield's skill and scholarship that it is hard to tell what subjects are his own special field, or when he is drawing, as he must at times, largely on the experience of others

Very little has escaped his net Common disorders are discussed at proper length, and uncommon ones are kept in their right *perspective*, but even the rarest finds a niche somewhere Although his avowed purpose is to consider only the clinical aspects of diagnosis, radiographic, endoscopic, and laboratory methods are briefly mentioned and some indication is given of their comparative usefulness There are also chapters on bodily constitution, the physical effects of environment, and disturbances of electrolyte balance, which are unusual and valuable Dr Wakefield has had the courage and originality largely to discard the customary academic lists of differential diagnoses There are copious references to recent publications in many languages, and though the illustrations are few they are clear and well chosen

The Principles and Practice of Surgical Nursing

D F ELLISON NASH, F.R C S , assistant surgeon, St Bartholomew's Hospital, London London Edward Arnold 1955 Pp 1007 30*s*

NURSES in training are nowadays no less harassed than medical students , and it is alarming that a textbook of nursing concerned only with surgical aspects should run to just over 1000 pages Nevertheless there is no adipose tissue in this book , all its pages are valuable, and some repetition, intentionally introduced for ease of reference, adds little to its weight It is a thoroughly sound and complete work which will undoubtedly find favour as a reference book Mr Ellison Nash has tried to present each subject from first principles and thus avoid a didactic approach and empiricism , and he has succeeded

Graphologie et physiologie de l'écriture

Dr H CALLEWAERT Louvain E Nauwelaerts 1954 Pp 168 $1 80

THE title of his book notwithstanding, Dr Callewaert does not believe that graphology yet exists He has studied by means of cinematographic records the individual movements and postures of writing, which he describes in the first part of the book, and he has acquainted himself with the assertions of the more serious graphologists, which he finds empty of logic and without any statistical foundation Dr Callewaert reviews the anatomical and physiological determinants of script which make it characteristic for the individual, and he draws a sharp distinction between speech, spontaneously acquired by imitation, and writing which has to be learnt by painful labour The constitutional element in psychomotor activity may give an individual imprint to each man's writing, but culture, schooling, and other extraneous influences may also lend the script a deceptive individuality Writing movements cannot be properly equated with expressive gestures for they lack the freedom of choice which the latter enjoy Dr Callewaert, in his just disapproval of the common claims of graphologists, unduly repudiates the expressive and individual quality in handwriting and its potential correlation with personality traits, but his interesting exposé deserves the attention of psychologists and neuropsychiatrists

Clinical Aspects of the Autonomic Nervous System

L A. GILLILAN, PH.D , M D , associate professor of anatomy, Graduate School of Medicine, University of Pennsylvania London J & A Churchill 1955 Pp 316 45*s*

Professor Gillilan, who is an anatomist, gives an excellent and detailed description of the topography of the autonomic nervous system and a full account of what is known of its physiological functions , and the book is valuable for this in itself When it comes to clinical applications, however, he is on less familiar ground, and is sometimes misleading It is, for example, untrue that " digitalis causes vomiting only when the dosage exceeds the therapeutic level " , and to say that " peptic ulcers tend to occur in the slender hyposthenic individual " is ingenuous His enthusiasm for dividing people into vagotonic and sympathotonic types may leave the unsophisticated reader with the impression that the complex interrelationships between mind, personality, body structure, functional order, and disorder are simpler than they really are The text is liberally illustrated by good line drawings

Peripheral Vascular Diseases

2nd ed EDGAR V ALLEN, B S , M A , M D , M S in med., F.A C.P , NELSON W BARKER, B.A , M D , M S in med., F.A C.P , EDGAR H HINES, JUN , B S , M A , M.D , M.S in med , F.A.C.P , professors of medicine, Mayo Foundation Graduate School, University of Minnesota Philadelphia and London W B Saunders 1955 Pp 825 91*s*

BASED on the experience of the senior authors and their colleagues at the Mayo Clinic over the last twenty-five years, this book gives a balanced general picture, and, in addition, sufficient information to satisfy the student interested in the historical development of physiology, pathology, and methods of investigation The first edition, published in 1946, quickly established this as the leading textbook in its field For this edition new subjects, such as aortography, the surgical treatment of aortic aneurysms, and vessel grafting, have been introduced Written with proportion and economy, the text points to the problems still outstanding, but does not leave the reader in a maze of controversy One attractive feature is that each chapter is headed by a photograph and a short biography of a pioneer in vascular work

---

Diagnostic électrocardiographique (2nd ed Paris Masson 1954 Pp 448 Fr 4800) —Feeling that the maze of *modern electrocardiography is becoming* labyrinthine in its complexity, Dr André Jouve, Dr Jacques Senez, and Dr Jean Pierron, and their collaborators, have introduced in the second edition of their textbook, the concept of the vectorial loop as a thread to guide the groping student through its mazes No single hypothesis so far advanced, they believe, fully explains the genesis of the electrocardiogram , nor do they accept the vectorcardiogram as such an explanation On the other hand they feel that the vectorcardiogram offers a convenient method of synthesising for the mind's eye the growing number of different electrocardiographic leads currently employed, and that as such it is a useful teaching instrument

The general arrangement of the book is unchanged The first section is devoted to the basic theory and technique of electrocardiography, both of which are handled in great detail, and this is followed by the main section on the normal and abnormal electrocardiogram, considered in relation to alterations in the electrical field of the heart in the body A chapter is given to the arrhythmias, and a short section on clinical applications of electrocardiography ends the book It is profusely, and on the whole clearly, illustrated, though some of the illustrations are overloaded with information (30 leads and 3 vectorial loops are shown in one cardiogram) Moreover, the arrangement of the leads is not uniformly depicted which means that they are often difficult and sometimes unnecessarily tedious to interpret

In its breadth of scope this book is a triumph But a risk is inherent in its catholicism , for in trying to supply the needs of both the clinician and the research worker it may not appeal fully to either

THE LANCET

LONDON SATURDAY JUNE 25 1955

Heroin

THE Government's announcement that after the end of this year the importation of heroin (diamorphine hydrochloride) is to be stopped and its manufacture restricted to small amounts needed for scientific purposes,[1] has been followed by strong protests in the medical and lay press. The ban is being imposed to give effect to a resolution adopted by the Economic and Social Council of the United Nations urging all governments to take this step with the object of checking illicit traffic in the drug. The Minister of Health had previously consulted the Standing Medical Advisory Committee of the Central Health Services Council which endorsed the view that suitable alternatives existed.[2] But on June 3 the representative body of the British Medical Association asserted that the Government could not claim to have consulted the medical profession without having consulted the Association. The representative body was satisfied that heroin should not be exported but called for continuation of its manufacture.[3] The chief arguments adduced in favour of this policy are that in some circumstances heroin is superior to any other drug, that there is little illicit traffic in the drug within this country and no illegal exportation of it, and that a legal ban on the manufacture of heroin can do little good, since this drug is readily made from opium or crude morphine.

Regarding efficacy opinion is by no means united. It seems to be fairly well established that heroin produces greater euphoria with a slighter risk of nausea than an equivalent dose of any other morphine preparation, and some clinicians are convinced that it is sometimes of peerless value—notably in controlling intractable pain and in treating tracheitis. On the other hand, controlled trials comparing heroin with other preparations have been lacking; and as early as 1931 a panel of experts (including the late Prof. W. E. DIXON, of Cambridge) ended its report to the League of Nations with the following words:[4]

> In view of the evidence which we possess, and especially the fact that all the beneficial actions of heroin can in our opinion be obtained by one or other of the drugs mentioned, we believe that heroin can be entirely dispensed with. If the doctors in countries where heroin is used are afforded the opportunity of examining and testing clinically the morphine derivatives to which we have drawn attention, we feel little doubt that they may be induced to dispense with the use of heroin entirely.'

Suppression of manufacture had already been mooted at an international level in 1923 and 1925, but in 1931 the proposal was again defeated, mainly on the ground that the drug was of medical value. But these decisions of course preceded the introduction of synthetic analgesics and of new morphine derivatives.

However much views may differ on the need for heroin to be at the doctor's disposal, we can all agree that in this country nearly all the heroin manufactured is used legally. There are here at present only 54 known heroin addicts, and the Home Secretary is satisfied that there is no substantial hidden addiction.[5] Nor is there any evidence that heroin is being exported illegally. In any case, as Dr D. R. LAURENCE[6] has pointed out, legally manufactured heroin contributes negligibly to the world's illicit traffic. It would, he says, be impossible to control such traffic without control of the illicit traffic in opium and morphine, from which heroin is readily manufactured. Dr LAURENCE's assertion is supported by an official report (1951)[7] that

> reports from governments during the last two years indicated that, thanks to stricter measures of control over manufacture of and trade in heroin put into effect by various governments, diversions from legal into illicit channels due to thefts, robberies, forged prescriptions or laxity in respect of issuance of medical prescriptions have been reduced to the minimum.

And Prof GEORGES BROUET, of Paris, has remarked:[8]

> If morphine continues in current use, heroin is so easy to prepare that there is little point in banning it internationally. If there was any absolute need for prohibiting its use in therapeutics in order to combat addiction, the principle might conceivably be accepted; but if the effect of such prohibition were to be illusory, as we fear it would, it is hard to see why patients who may benefit from it need be deprived of it.'

What then led the Economic and Social Council to make its recommendation? It was acting on a resolution by the sixth World Health Assembly that "the abolition of legally produced diacetylmorphine . . . would facilitate the struggle against its illicit use."[9] Both the Assembly and the W.H.O. Expert Committee on Drugs Liable to Produce Addiction (whose reports were before the Assembly) were impressed by the extensiveness of the illicit use of the drug: in 1951 alone 120 kg. was seized, including 62 kg. in Europe and 26 kg. in the United States.[7] This heroin is believed to have originated mostly in the Far East and on the Mediterranean seaboard. Such traffic can be stopped only by universal enforcement of rigorous measures. At present the countries of the world fall into three groups: (1) those (including the U.S.A.) where all heroin is illicit; (2) those (including Britain and France) where the law seeks to control manufacture and distribution; and (3) those where there is no effective control, and which in some cases export morphine or heroin illicitly on a large scale. Britain's decision to impose the ban can have no direct effect on this traffic; but it might persuade our close neighbour France, which has decided against the ban (and where 1051 g. of heroin was seized in 1951), to reverse her decision. The more countries that impose the ban the easier would be the task of those checking illicit traffic; for wherever the ban operates any heroin found is certainly illicit. Those countries that now act on the Council's recommendation may

also hope to influence the few countries in the third category—where there is little or no control of production or distribution—to raise themselves eventually to the second or first category Most nations are less insensitive than we sometimes suppose to the climate of opinion around them , if only one or two isolated countries were left trafficking freely in heroin the weight of world opinion might lead them to re examine their practice By now imposing the ban Britain is making her own small contribution to this end

But the question remains by taking this action shall we be depriving patients of an essential drug ? An impartial observer might reply that we do not know Those who would suppress the use of heroin have brought forward persuasive evidence that the risk of addiction is greater than with any other morphine preparation, and some (but no overwhelming) evidence that another drug can always take its place equally well[10] Thus we are in a position where each side—those who insist on having heroin at their command and those who insist that this is needless—are firmly convinced without satisfactory objective evidence It may not be too late to seek that evidence by a controlled trial Such a trial would be lengthy and very difficult , but it would not be impeded by ethical considerations, since any differences between heroin and its alternatives are not gross If the trial clearly showed heroin to have unique virtues the first clause in the World Health Assembly's resolution—" Being convinced that diacetylmorphine is not irreplaceable for medical practice" —would fail, and we should not be blameworthy if we reverted to the manufacture of heroin for use within our borders If on the other hand no clear advantage emerged, we should maintain the ban without further question Meanwhile, one thing we must not do is to insist on retaining the status quo on the basis of the present unsatisfactory evidence As a member of the United Nations we cannot divorce our own well being from that of our neighbours By article I of the United Nations Charter we have pledged ourselves " to achieve international cooperation in solving international problems of an economic, social, cultural or humanitarian character " It is only by readiness to cooperate—to give and take—that the United Nations or its agencies can be made to work at all

Cobalt and Anæmia

COBALT deficiency is known to occur in sheep and cattle in Denmark, Australia, and some other places where the soil and grass are deficient in this element The syndrome, which has various local names, such as " bush sickness," is characterised by some anæmia, and by poor growth, lack of appetite, and emaciation[11] The fact that vitamin B_{12} contains 4 5% of cobalt shows that cobalt is necessary for normal nutrition in man as well , but since the daily requirement of vitamin B_{12} in man has been put at no more than 1 µg , cobalt can properly be regarded as a " trace element " Cobalt has been used for the treatment of anæmias which are refractory to the normal hæmatinics, especially iron , such anæmias develop in chronic infections, after burns, in kidney disease, and in some children Compared with the daily requirement of about $^1/_{25}$ of a microgramme the doses of 20–60 milligrammes daily of cobaltous chloride (about 9–25 mg of cobalt) that are given therapeutically are relatively enormous, and it is clear that any action cobalt has on refractory anæmias must be quite different from its physiological action

WINTROBE and his co-workers[12] produced local inflammation in rats with turpentine and showed that the consequent anæmia could be overcome by giving cobalt salts They were surprised to find that polycythæmia was induced in these animals, and further work[13] showed that the absorption of iron from the alimentary tract was increased by giving cobalt Later work suggested that daily doses of up to 100 mg of cobaltous chloride given to patients with anæmia associated with chronic infections produced a reticulocytosis in about six days and an increase in the circulating red cells and hæmoglobin , but, judging by the few reports published in the past five years, this treatment has not been widely applied in practice

GARDNER[14] investigated the use of cobalt for the relief of anæmia associated with chronic renal disease Such an anæmia has usually been treated with repeated blood-transfusions, but the results are not satisfactory and reactions may add to the burden of an already embarrassed kidney He soon found that cobalt had to be given for at least four weeks if any reasonable erythropoietic response was to result , so patients whose kidney disease was causing rapidly increasing azotæmia and acidosis were not included in the trial He found 17 cases in a sufficiently stable state , 8 were diagnosed as chronic pyelonephritis , 6 had chronic, and 1 acute, glomerulonephritis , 1 had the nephrotic syndrome , and 1 had polycystic kidneys The red cell counts before treatment varied from 2,750,000 to 3,920,000 per c mm and their hæmoglobin levels from 6 g to 11 g per 100 ml Most of these patients showed a definite response , for instance, in the patient with an initial hæmoglobin of 6 g per 100 ml the level rose to 9 6 g , and in the patient with 11 g per 100 ml initially the level rose to 13 1 g , red cells rose proportionately rather less If treatment was continued some further improvement occurred for three months , if treatment was stopped the blood-levels declined slowly, reaching the original level in about twelve weeks The bone marrow, examined in some patients, showed increased proportions of erythroblasts GARDNER observed that cobalt salts, especially in solution, are very liable to cause anorexia, nausea, and vomiting , he overcame this difficulty by using enteric coated tablets and giving them only at meal times There was no evidence that the cobalt affected the kidney disease, one way or the other, but the patients felt better with a higher hæmoglobin

COLES[15] has reported results with cobalt treatment of some of the anæmias of childhood Altogether 50 patients were treated In 31 the anæmia was associated with infection, 10 were anæmic premature infants, n 3 the anæmia was due to rhesus incompatibility and the remainder were a miscellaneous group COLES states that these types of anæmia usually respond poorly to iron, liver, and other hæmatinics but she describes no evidence that these particular 30 patients were in fact refractory The infections that caused anæmia were predominantly otitis media and bronchopneumonia, and the blood picture was normochromic COLES does not give individual counts, but only average figures on which it is more difficult to judge the value of the treatment Most of the patients received 25 mg of cobalt sulphate daily for three weeks, and no toxic effects were noted The average rise of hæmoglobin was from 9 23 g per 100 ml to 11 24 g per 100 ml and the greatest rise occurred in the first week. The 9 premature infants received 20 mg of cobalt sulphate daily for three weeks, the average hæmoglobin level rose from 9 17 g per 100 ml initially to 12 28 g per 100 ml, again with the greatest increase in the first week The other patients also responded satisfactorily Cobalt was also given to a child with a chronic hypoplastic anæmia who was being treated with repeated blood transfusion there was no response—which agrees with the experience of most others COLES examined the bone-marrow before and after cobalt treatment in 12 patients There was an increase of erythropoietic cells in all, in the patients with infections the increase was mostly in the pro-erythroblasts and the earlier normoblasts whereas in the premature infants the later normoblasts were most increased. COLES suggests that this denotes that cobalt has a different action in the two groups in the premature infants iron supplies are adequate and cobalt enables the erythroblasts to utilise iron more efficiently in the anæmia of infection cobalt directly stimulates erythropoiesis in a previously depressed marrow

Cobalt as a stimulator of erythropoiesis has been tried for the treatment of red cell aplasia in adults This is a progressive anæmia without hæmorrhages or other complications, in which examination of the marrow shows few erythroblasts of any stage but much less affection of granulocytes and megakaryocytes SEAMAN and KOLER[16] reported such a case which responded satisfactorily to cobalt therapy, and FOUNTAIN and DALES[17] also reported a response when cobalt chloride was given in a dose of 100 mg daily for two months

All these reports will encourage further trial of cobalt in the treatment of patients with these anæmias that respond poorly if at all, to the usual hæmatinics, who usually have to be treated by repeated transfusions But two warnings must be given In the first place it is desirable that patients with these refractory anæmias should receive cobalt therapy early in the course of their disease the value of treatment with cobalt is not easily assessed when it follows soon after a course of blood transfusions, the exhibition of cortisone or splenectomy In the second place in the dosage used cobalt can have unpleasant toxic effects The immediate effects such as nausea vomiting, and anorexia, can be averted by using enteric coated tablets Some patients have unpleasant tinnitus or flushing of the face[14] A more serious goitrogenic effect has been reported.[18] KRISS et al were administering enteric coated tablets of cobaltous chloride in doses varying from 30 to 100 mg daily for the treatment of sickle cell anæmia Goitre and hypothyroidism developed in 2 of their patients, in one treatment for myxœdema was needed, and in the other the thyroid tumour appeared clinically to be a carcinoma They found 3 other cases of thyroid hyperplasia by examining post mortem tissues The explanation of this action is uncertain. It is known that cobalt given in doses larger than those administered clinically, can cause polycythæmia in rats It seems to be agreed that this action is due to anoxia from inhibition of some of the enzymes concerned with the transport of oxygen, thus LEVY et al[19] found that cobalt inhibited two sulphydryl dependent enzymes—succinic dehydrogenase and choline oxidase The erythropoietic stimulation may therefore be a response to a toxic anoxæmia The goitrogenous action noted by KRISS et al may be due to interference by cobalt with the enzyme system that forms mono-iodotyrosine If the stimulating' action of cobalt on erythropoiesis in refractory anæmias depends on its toxic properties, then it should clearly be administered cautiously and should not be included in iron or other preparations for the treatment of anæmia Like all other hæmatinics, it should be given alone

CANCER OF THE LARYNX

IN the past it has been very difficult to assess the results of different forms of treatment for cancer of the larynx This was due partly to the relatively small number of cases in individual series but very largely to differences in definition classification and grading of the tumours In the past decade or two there has been a growing tendency to centralise the management of these relatively uncommon tumours and laryngologists and radiotherapists are slowly approaching unanimity on classification and grading In the past three months three large series of results have been published in which the classification was the same

Growths of the laryngopharynx were previously known as extrinsic laryngeal cancers now they are described by most laryngologists as cancers of the pharynx Anatomically they belong to the pharynx clinically they behave quite unlike the true laryngeal growths They produce symptoms late they metastasise early to the regional lymph nodes, they respond very poorly to any form of treatment and they have a most depressing prognosis The term laryngeal cancer is now usually limited to those growths which were previously known as intrinsic or endolaryngeal cancers Most of these produce symptoms early metastasise late are eminently treatable and have a much better outlook Indeed in the case of early carcinoma of the vocal cords the prognosis is better than with cancer at any other site.

In 1942 Nielsen and Strandberg[20] divided cancer of the larynx into four stages

In *stage I* the tumour is limited to the anterior two thirds of one of the true vocal cords, and the mobility of the affected cord is unaffected There may be invasion of the anterior commissure but no further extension.

also hope to influence the few countries in the third category—where there is little or no control of production or distribution—to raise themselves eventually to the second or first category Most nations are less insensitive than we sometimes suppose to the climate of opinion around them , if only one or two isolated countries were left trafficking freely in heroin the weight of world opinion might lead them to re examine their practice By now imposing the ban Britain is making her own small contribution to this end

But the question remains by taking this action shall we be depriving patients of an essential drug ? An impartial observer might reply that we do not know Those who would suppress the use of heroin have brought forward persuasive evidence that the risk of addiction is greater than with any other morphine preparation, and some (but no overwhelming) evidence that another drug can always take its place equally well [10] Thus we are in a position where each side—those who insist on having heroin at their command and those who insist that this is needless—are firmly convinced without satisfactory objective evidence It may not be too late to seek that evidence by a controlled trial Such a trial would be lengthy and very difficult , but it would not be impeded by ethical considerations, since any differences between heroin and its alternatives are not gross If the trial clearly showed heroin to have unique virtues the first clause in the World Health Assembly s resolution—" Being convinced that diacetylmorphine is not irreplaceable for medical practice" —would fail, and we should not be blameworthy if we reverted to the manufacture of heroin for use within our borders If on the other hand no clear advantage emerged, we should maintain the ban without further question Meanwhile, one thing we must not do is to insist on retaining the status quo on the basis of the present unsatisfactory evidence As a member of the United Nations we cannot divorce our own well-being from that of our neighbours By article I of the United Nations Charter we have pledged ourselves ' to achieve international cooperation in solving international problems of an economic, social, cultural or humanitarian character " It is only by readiness to cooperate—to give and take—that the United Nations or its agencies can be made to work at all

Cobalt and Anæmia

COBALT deficiency is known to occur in sheep and cattle in Denmark, Australia, and some other places where the soil and grass are deficient in this element The syndrome, which has various local names, such as " bush sickness," is characterised by some anæmia, and by poor growth, lack of appetite, and emaciation [11] The fact that vitamin B_{12} contains 4 5% of cobalt shows that cobalt is necessary for normal nutrition in man as well , but since the daily requirement of vitamin B_{12} in man has been put at no more than 1 µg , cobalt can properly be regarded as a " trace element ' Cobalt has been used for the treatment of anæmias which are refractory to the normal hæmatinics, especially iron , such anæmias develop in chronic infections, after burns, in kidney disease, and in some children Compared with the daily requirement of about $^1/_{25}$ of a microgramme the doses of 20–60 milligrammes daily of cobaltous chloride (about 9–25 mg · of cobalt) that are given therapeutically are relatively enormous, and it is clear that any action cobalt has on refractory anæmias must be quite different from its physiological action

WINTROBE and his co-workers [12] produced local inflammation in rats with turpentine and showed that the consequent anæmia could be overcome by giving cobalt salts They were surprised to find that polycythæmia was induced in these animals, and further work [13] showed that the absorption of iron from the alimentary tract was increased by giving cobalt Later work suggested that daily doses of up to 100 mg of cobaltous chloride given to patients with anæmia associated with chronic infections produced a reticulocytosis in about six days and an increase in the circulating red cells and hæmoglobin , but, judging by the few reports published in the past five years, this treatment has not been widely applied in practice

GARDNER [14] investigated the use of cobalt for the relief of anæmia associated with chronic renal disease Such an anæmia has usually been treated with repeated blood-transfusions, but the results are not satisfactory and reactions may add to the burden of an already embarrassed kidney He soon found that cobalt had to be given for at least four weeks if any reasonable erythropoietic response was to result , so patients whose kidney disease was causing rapidly increasing azotæmia and acidosis were not included in the trial He found 17 cases in a sufficiently stable state , 8 were diagnosed as chronic pyelonephritis , 6 had chronic, and 1 acute, glomerulonephritis , 1 had the nephrotic syndrome , and 1 had polycystic kidneys The red cell counts before treatment varied from 2,750,000 to 3,920,000 per c mm and their hæmoglobin levels from 6 g to 11 g per 100 ml Most of these patients showed a definite response , for instance, in the patient with an initial hæmoglobin of 6 g per 100 ml the level rose to 9 6 g , and in the patient with 11 g per 100 ml initially the level rose to 13 1 g , red cells rose proportionately rather less If treatment was continued some further improvement occurred for three months , if treatment was stopped the blood-levels declined slowly, reaching the original level in about twelve weeks The bone marrow, examined in some patients, showed increased proportions of erythroblasts GARDNER observed that cobalt salts, especially in solution, are very liable to cause anorexia, nausea, and vomiting , he overcame this difficulty by using enteric-coated tablets and giving them only at meal times There was no evidence that the cobalt affected the kidney disease, one way or the other, but the patients felt better with a higher hæmoglobin.

COLES [15] has reported results with cobalt treatment of some of the anæmias of childhood Altogether 50 patients were treated In 31 the anæmia was associated with infection, 10 were anæmic premature infants, in 3 the anæmia was due to rhesus incompatibility, and the remainder were a miscellaneous group Coles states that these types of anæmia usually respond poorly to iron, liver, and other hæmatinics, but she describes no evidence that these particular 60 patients were in fact refractory The infections that caused anæmia were predominantly otitis media and bronchopneumonia, and the blood picture was normochromic Coles does not give individual counts, but only average figures on which it is more difficult to judge the value of the treatment Most of the patients received 25 mg of cobalt sulphate daily for three weeks, and no toxic effects were noted The average rise of hæmoglobin was from 9 23 g per 100 ml to 11 24 g per 100 ml and the greatest rise occurred in the first week The 9 premature infants received 20 mg of cobalt sulphate daily for three weeks the average hæmoglobin level rose from 9·17 g per 100 ml initially to 12 28 g per 100 ml., again with the greatest increase in the first week. The other patients also responded satisfactorily Cobalt was also given to a child with a chronic hypoplastic anæmia who was being treated with repeated blood transfusion, there was no response—which agrees with the experience of most others. Coles examined the bone-marrow before and after cobalt treatment in 12 patients There was an increase of erythropoietic cells in all, in the patients with infections the increase was mostly in the pro-erythroblasts and the earlier normoblasts whereas in the premature infants the later normoblasts were most increased Coles suggests that this denotes that cobalt has a different action in the two groups in the premature infants iron supplies are adequate and cobalt enables the erythroblasts to utilise iron more efficiently, in the anæmia of infection cobalt directly stimulates erythropoiesis in a previously depressed marrow

[20] Nielsen J, Strandberg O *Acta radiol Stockh* 1942 23 189

In *stage 2* the tumour involves the anterior commissure and, perhaps a greater or lesser part of the anterior two thirds of the true vocal cord The mobility of the cord is still unaffected

In *stage 3* the tumour extends beyond the vocal cord, which is more or less fixed Involvement may be unilateral or bilateral The lymph nodes, however, are not affected

In *stage 4* the tumour extends beyond the larynx, commonly with lymph node involvement

Falbe Hansen,[21] of Copenhagen, describes the results of surgical treatment of laryngeal cancer Operation is indicated, he says, in subglottic cancer and in cancer of the vocal cord with complete or almost complete fixation It is further indicated where a "test treatment" with radiotherapy has shown no effect, and in cases of residuum or recurrence after such therapy 38 laryngectomies were done between January, 1942, and January, 1949, with a minimum follow up period of five years 35 of the patients were men only 3 women Of the 38 cases, 36 belong to the 3rd or 4th stage In each of the 2 cases in stage 1 or 2 there had been a recurrence after radiotherapy Five years or more after laryngectomy 21 of the patients—55% of the total—were alive and well, 6 other patients had died from other causes, without signs of residuum or recurrence, less than five years after operation The lymph nodes were removed, together with the larynx, in 7 patients with stage 4 cancers 1 of them died fifteen days after the operation from severe sepsis, and recurrences developed in 2, but 3 were alive and well at the end of six to eight years, and 1 died of appendicitis seven months after operation, without any signs of recurrence Preoperative radiotherapy was given in 14 cases, and 9 of these patients are alive and symptom free after more than five years, while 4 have died, without any sign of recurrence, at various intervals after the operation These results are impressive

Wang and O'Donnell,[22] two radiotherapists at the Massachusetts General Hospital, record the results in 253 cases of cancer of the larynx, with the emphasis on radiotherapy These patients were treated between 1931 and 1949, again with a minimum follow-up period of five years They advocate tomography and lateral soft tissue radiography for determining the extent of the tumour 95% of their patients were men Of 35 patients stage 1 growths treated by radiotherapy, 80% were symptom free after five years, of 15 patients treated by surgery, 86% were alive and well

Of 19 patients with stage 2 growths treated by radiotherapy, 68% were alive and well after five years, of 12 patients treated by surgery, 58% survived Of 58 patients with stage 3 growths treated by radiotherapy, only 24% survived for five years, no less than 53% of those treated surgically survived for the same period Of 46 patients with stage 4 growths treated by radiotherapy, 15% were free of recurrence five years after treatment, of 7 patients treated surgically, 13% survived

Nielsen[23] believes that the main problem in the treatment of these tumours centres round coöperation between surgeon and radiotherapist, to obtain "the highest numbers of cures with the maximum of functional results" At the moment, he says, opinions seem to vary between the two extremes of 100% surgery and 100 % irradiation Nielsen, a radiotherapist, has collaborated with Falbe Hansen, his laryngologist colleague, in treating his cases Since 1942 all stage 1 and stage 2 cases have been referred primarily for radiotherapy, the majority of stage 3 cases have also been primarily irradiated, except for subglottic cancers and cancers of the vocal cords with complete or almost complete fixation, primary irradiation was preferred in stage 4 cancers arising from the subglottic region Of the 235 patients in this series the majority were treated by radiotherapy In the two earlier stages about 80% survived for five years after radiotherapy, and a further 10% died from another cause before the five-year limit Of 18 cases of subglottic cancer, a third were cured by surgery, and only 1 single case by radiotherapy

Several points emerge from these three large series, amounting to over five hundred cases assessed by one classification In cases of early cancer of the true vocal cord, without limitation of mobility, the results of radiotherapy differ very little from those of surgery in terms of life and "five year cures", but the functional results, as regards the voice, are much better with radiotherapy "In this respect I think most laryngeal surgeons are agreed," says Falbe Hansen, but, he adds, "only very few seem to act accordingly" Surgery alone gives incomparably better results than radiotherapy alone in stage-3 growths which have infiltrated the vocal cords or extended beyond them, yet are still within the confines of the larynx But, as Wang and O'Donnell say, since a quarter of stage 3 growths can be controlled by radiotherapy, with preservation of voice, "a fair trial of this conservative method should be carried out If the tumour does not respond favourably to radiation, total laryngectomy may still be done" Mono block dissection of larynx and glands will probably be practised more commonly in the future in stage 4 growths, and even better results will be obtained in these more advanced tumours by a formal combination of radiotherapy and surgery As in other aspects of otolaryngology, the emphasis is shifting to preservation of function

HYPOPHYSEOTOMY IN DIABETES

In young adults with "malignant" diabetes, for whom nothing but further deterioration can otherwise be expected, Prof H Olivecrona and his colleagues in Stockholm have obtained considerable improvement by removal of the pituitary gland [1]

In the Ciba Foundation lecture, written with Dr Rolf Luft, which he gave in London on June 15, he explained that this work, starting in 1951, was based on experimental evidence of the diabetogenic action of growth hormone and adrenocorticotrophic hormone,[2] and on reported regression of diabetes in several cases of pituitary deficiency So far, he has operated on 17 patients, all with advanced diabetic retinopathy and all with renal damage in some degree—often far advanced Of the 3 operative deaths 2 were from complications such as may follow any major operation, and it should be remembered that the juvenile diabetic with vascular disease is not a good subject for surgery Of the 4 patients who have died since leaving the clinic (2 of them surviving eighteen months), 3 were treated too late to derive substantial benefit The remaining 10 patients are alive after periods ranging from five months to three and a half years, during which they have had substitution therapy with cortisone, thyroxine, and (in most cases) testosterone or stilbœstrol, together with smallish doses of insulin Up to date, the eye ground changes appear to have been arrested exudates have decreased or remained stationary, proliferation of blood vessels is no longer progressive, and hæmorrhages have slowly disappeared, though new ones have occasionally been observed in the first few months In every case, except 1 in which hypophysectomy was incomplete, renal blood flow has increased or remained stationary, and of the 8 patients who had arterial hypertension all now have blood-pressures within normal limits From this preliminary assessment of hypophysectomy as a means of preventing blindness and irreparable renal damage "we think that our results are encouraging" said Professor operations Better results, he believes could be expected if the operation were carried out earlier

ANGIOCARDIOGRAPHY IN CHEST DISEASE

It might have been thought that angiocardiography would prove of great value for investigating pulmonary disease, but so far this application has been comparatively limited. Abels[1] now describes angiocardiographic studies in cases of pulmonary and mediastinal abnormalities discovered in mass-radiography surveys Of the 12 illustrative cases that he cites 4 had lesions in the lung fields, and in 3 of these a presumptive diagnosis of arteriovenous aneurysm or hæmangioma was confirmed by displaying the vascular tree Tomography as Abels points out is very helpful in such cases since it often shows vascular tufts associated with the lesions The fourth pulmonary lesion was a curvilinear opacity near the heart shadow which was shown to be an anomalous pulmonary vein In the other 8 cases radiographs of the chest showed mediastinal or paramediastinal abnormalities and in this type of case as Abbott et al[2] had previously found angiocardiography was of more decisive diagnostic importance suspected vascular lesions were accurately localised—for example a putative aortic aneurysm was proved to be an aneurysm of the pulmonary artery and a thymoma associated with a systolic murmur was demonstrated before operation not to be a lesion of a great vessel

The scope of angiocardiography in diseases of the chest may be extended in the future. Cudkowicz and Armstrong[3] have reported differences between the vascular patterns of primary and of secondary neoplasm and Sleeser et al[4] have averted fruitless thoracotomy in some patients with bronchial carcinoma by demonstrating neoplastic involvement of the great vessels But, as Abels points out, angiocardiography is not without risk. It should be undertaken only where it seems essential in order to establish the diagnosis.

DELIVERY BY SUCTION

In the past many ingenious and elaborate obstetric forceps have been devised—one of these was so complex that a screwdriver for running repairs was included in its handle Nowadays forceps are lighter and shorter Even the axis traction instrument devised by Tarnier and so beautifully worked out mathematically by Milne Murray is no longer necessary now that the high forceps operation is rarely practised It is generally agreed that if more than gentle traction is necessary this usually indicates that the time or method of delivery has been misjudged For the simple low extraction Wrigley's forceps have become popular and Finderle[5] describes an even lighter implement which can be applied to the vertex by suction. It consists of a horn shaped cup which at its wider end is covered by rubber and at its narrow end is attached by tubing to a syringe. The position of the head is determined and the wide end of the horn is introduced through the introitus and applied to the head A partial vacuum is created by two or three thrusts of the syringe and maintained by a stopcock. There are light metal finger rests on the narrow end of the horn and by traction on these the head is delivered

Finderle states that in the last 4000 or more deliveries at his clinic the use of forceps has been completely discontinued He reports 132 successful extractions 103 of the patients were primigravidæ, and the majority of the babies were mature and of average weight There were no deaths or complications attributable to the extractor and from the information that the use of forceps has been discontinued we must conclude that there were no failed extractions Sometimes an artificial caput succedaneum has formed on the baby's scalp but this has always disappeared within a few hours. The level of the head at delivery is not specified, but the cæsarean section rate at the clinic is only just over 2% so apparently the use of the extractor is not confined to cases in which the head is on the perineum Anæsthesia has not always proved necessary, but episiotomy under local anæsthesia is usually done in the primigravida before the extractor is applied Finderle claims that the head can be readily rotated by means of the applied horn and he also reports 4 successful applications to the breech

It is unlikely that this instrument (which resembles others previously devised) can completely replace the forceps but Finderle's results suggest that its value should be further tested.

A NEW ENTERIC ORGANISM

THERE is much to be said for the suggestion by Edwards and West[1] that the enteric bacteria should be regarded as a continuous series of interrelated types rather than be classified in rigid groups such as salmonella arizona and paracolon ' While some—e.g , *Salmonella typhi* or *S typhimurium*—have reasonable claims to be regarded as species since they are fairly constant in habit in vivo and in vitro and are readily distinguished from related organisms, we should remember that they owe their places as ' type specimens to their common occurrence as parasites of man in the temperate zone. Deliberate search and chance observation have now raised the number of more or less typical members of the salmonella group to about 300 and at the same time have yielded strains which have some but not all of the biochemical and antigenic characters typical of Salmonella Many such are probably overlooked for obvious reasons some are found once only studied in some detail and then put aside in case another turns up It seldom does and for this reason a paper by McDonald et al[2] is of interest Since the end of 1951 strains of ' atypical paratyphoid bacilli ' have been reported from places as distant as Inverness and Newport, Mon They have been isolated from 99 people of whom 43 had acute gastro-enteritis and the rest no symptoms at all. Most of the infections were single but a small epidemic in Gateshead involved 14 people[3] The organism presumed to be responsible differs from *S paratyphi B* in that it fails to ferment dulcitol cannot be typed by bacteriophage and has the antigenic formula IV V XII b :—(*instead of* I IV V XII : b : 1 2)

The distinction of infections due to this organism from paratyphoid fever may be of administrative importance. As Savage pointed out,[4] many infections with *S paratyphi B* cause only an acute enteritis with a short incubation period The responsibility for differentiating infections by the enteric group of organisms must lie with the laboratory and this paper is a good advertisement for the Salmonella and Enteric Reference Laboratories Few diagnostic bacteriologists are adepts at the finer points of antigenic analysis or bacteriophage typing The reference laboratories not only afford these services to all but are best placed to observe the changing prevalence of bacterial species and the emergence of types not seen before It would be nice to know how often in the past this new organism has been called a paratyphoid bacillus That it is a cause of human illness we have little doubt, and it may be found to have an even wider distribution Whether it is labelled *S paratyphi B var*, or *S java* (which it seems to resemble), or "paracolon" is unimportant (except to the systematists) now that occurrence and identity have been recorded It matters more that all should realise that the ability to cause disease is not limited to organisms in the Kauffman-White list of salmonellæ

It would indeed be remarkable if pathogenicity were associated quite strictly with biochemical habit or antigenic structure Two of the more successful and specialised parasites—*S typhi* and *S pullorum*—are both nonconformist in vitro Until we know far more than at present it will be wise to regard all the organisms which share the major antigenic factors and some of the biochemical habits of salmonella as potential agents of disease

IMMEDIATE DENTURES

THE Ministry of Health memorandum to local authorities which we summarised last week, gave some depressing figures to show how much money had been spent on dentures during the first five years of the National Health Service The total was about £100 million, and, if the present demand is maintained, it is likely that, in a few years' time 1 in 6 of the population will wear dentures, and two fifths of them will be under 45 We cannot, of course, know how much of this prosthetic work was avoidable, or just how many sets of teeth have been ruined by neglect, but it is plain enough that the dental health of the nation is far worse than it should be Energetic propaganda by both doctors and dentists is undoubtedly part of the answer, but, however effective that may be, we shall still have to provide for the edentulous patient for many years to come

By means of acrylic resins, dentures can now be made far more pleasing æsthetically than when they were made in vulcanite, but patients are understandably becoming more exacting, and a denture is expected to reach a high standard in comfort and efficiency as well as in appearance As Gimson[1] points out, many of the difficulties of constructing full dentures are the result of leaving the patient edentulous for the customary time of three to six months Immediate dentures have many advantages, apart from the obvious one of escaping the toothless weeks after extractions Anatomical changes in the temporo mandibular joint and in the shape of the tongue are avoided, and there is no opportunity for the patient to learn incorrect habits of mastication, nor for the facial contour to collapse The task of the dental technician is made easier, for the natural teeth, or an impression of them, can be used as a guide to the occlusion and, if necessary, to the shape and position of the teeth

Various techniques may be followed, but one which gives good results is to extract the posterior teeth first, and then, after a lapse of six to eight weeks, so make a partial denture After a further period of a week or two, the anterior teeth are extracted and the denture completed This is quite satisfactory provided that the patient understands that it will be necessary to have the dentures relined after three or four months, and provided that certain precautions, as outlined by Gimson, are taken An alternative method, perhaps rather more popular in the United States than in this country, is to perform an alveolectomy when the anterior teeth are extracted This has advantages when the natural incisors are unduly prominent because of malformation of the pre maxilla, and it also makes it possible to fit a labial flange to the upper denture But the nervous patient does not always like the extra operation, and it is perhaps better to reserve alveolectomy for those in whom a good cosmetic and functional result could not be obtained by simpler methods

When an upper immediate denture is made without an alveolectomy, it is usual to "socket" the artificial teeth, and it is at this stage, Gimson emphasises, that considerable damage may be done to the ridge There is a temptation to fit the artificial roots well up into the sockets, probably in the hope that when absorption is complete the denture will still be a reasonable fit Unfortunately what happens is that at the end of seven or eight weeks, the ridge shows deep and permanent cavitation and is anything but suitable as a stable base for a denture Gimson describes the technical details necessary to ensure a correct fit for the anterior teeth —but, as he is careful to stress, it is essential to make regular adjustments to the denture as absorption proceeds A new denture will probably be needed in anything from six to twelve months after the insertion of the immediate denture For success, the patient's cooperation is essential, he must be prepared to return frequently for adjustments, and the dental surgeon must realise how vital these adjustments are

RECONSTRUCTION OF HAND DIGITS

RECONSTRUCTIVE surgery of the hand is applied to two broad groups of patients—those with congenital deformities, and those with mutilated fingers The former group often have associated malformations, but show considerable adaptive powers which may make reconstruction unnecessary or undesirable Most of the operations designed to replace or refashion digits depend on the use of structures in the hand itself, but several attempts have been made to use the toes to repair a defective or damaged hand Esser and Ranschburg[1] have described a successful graft of four toes to a hand. Blair and Byars[2] and Young[3] have each described single cases of a finger successfully reconstructed with a toe, while a less successful case has been reported by Neuhof[4] Clarkson[5] has developed this technique, mainly for thumb defects A dorsal flap is made on the foot, extending proximally almost to the ankle joint, and is delayed in one or two stages The hand is prepared by creating a matching skin defect, and is brought down to the foot The foot tendons are divided in the ankle region, and are sutured to those in the hand The skin flap is then sewn in place Six weeks later the toe is amputated through the metatarsophalangeal joint, and the wound is covered by grafting The new thumb may be modelled as necessary In Clarkson's patients nerve suture has not been performed It would be useful to know the amount of sensory perception in the new digit Bunnell[6] condemned this type of operation where there was subsequently no reliable tactile and proprioceptive sensation Nevertheless, the foot-to-hand graft may be of great value to patients in whom local operations are impracticable

On June 20 the DUKE OF EDINBURGH was installed as an honorary fellow of the Royal College of Surgeons of Edinburgh which is celebrating its 450th anniversary

The Medical Disciplinary Committee of the General Medical Council will meet on Tuesday, July 12, at 10 30 A.M

DISPOSAL OF THE CHRONIC CASE

J. R. D. BAYNE
M.D. McGill
SENIOR HOUSE-OFFICER

MARJORY WARREN
M.R.C.S.
CONSULTANT PHYSICIAN

GERIATRIC UNIT, WEST MIDDLESEX HOSPITAL, ISLEWORTH

In modern medical practice suffering tends to be reduced to a mathematical equation. We speak of morbidity and mortality rates, incidence of disease and survival time. Assessment of disease in these terms gives direction to further study and indicates its urgency. But there is a danger of mistaking a calculated solution for a remedy, forgetting that finally we are treating not a disease but a person. To speak of the "disposal" of patients suggests that the danger is real.

Yet a hospital unit or firm may say that if the chronic cases could be disposed of there would be room for all the acute cases, and that the need today is for chronic hospital beds. The implication is that these patients are beyond further therapy and can never return to their home community. If it is held that no therapy is needed the medical staff of a chronic-sick hospital should be small. The medical officer would be expected merely to look after the patients in any acute intercurrent illness. No patients would be discharged.

But who decides that a person is irremediable and beyond therapy? Will the decision be based on the knowledge that this type of case is hopeless, or that this particular patient has not responded? If new therapeutic methods offer new hope, who will review the case? And what will be the possibility of the patient gaining reassessment if he asks for it?

The following case-history is an example of what may occur. It offers no new therapeutic method, no tit-bits of pathogenic mystery, yet it deserves the attention of the busy physicians who every day dispose of chronic cases and sometimes may unwittingly add misery to suffering.

CASE HISTORY

In July, 1954, the geriatric unit was asked by the regional hospital board to accept a case of long-standing hemiplegia from a chronic-sick hospital in the provinces which was closing for repairs. The patient's home was believed to be at Twickenham, Middlesex. She was admitted on July 28. A brief accompanying letter said: "She has been bed ridden for years due to left hemiplegia and mentally is still unstable."

The patient was 74 years of age, and able to give a clear and consistent history. She said that until she was on the train she did not know to where she was being moved. She was born with a left-sided weakness and shaking of the left arm. Her two sisters and three brothers were normal. They regarded her as likely to be a burden on them and she determined to be independent. At the age of 16 she entered domestic service and became self-supporting; later on she rented a room and worked as a charwoman. She was able to get about without sticks and to climb the two flights of stairs to her room. She never moved from London. After her mother's death in 1923 she became gradually estranged from her relatives.

In 1925 she entered hospital for the first time because of an attack of influenza. She was persuaded to accept surgical treatment for her deformed left foot, but it was not a success and the wound did not heal. She continued to work, but it became difficult to find jobs because of her disability and local sepsis. In 1935 she re-entered hospital for treatment of a chest infection and on recovery she was advised to accept amputation of the foot or leg. She refused and was not given her discharge because her leg was regarded as "a danger." Her room was given up and her personal belongings scattered.

In 1940, when the chronic sick were evacuated from the bombing areas, she was transferred from London to a chronic-sick hospital in the provinces, where she remained until 1954. She asked repeatedly if she might get up, but was not allowed even to sit in a chair until lately. The following excerpts from the scanty records, which were sent complete with her, are typical:

1942.—She was seen five times and noted as being in satisfactory condition "and her speech intelligent."

1943.—She had a "violent hysterical attack."

1948.—She was treated with tincture of stramonium.

1949.—There were trophic changes of the feet with bilateral foot-drop.

1950.—A complete re-assessment was carried out by a consultant physician interested in rehabilitation. He wrote:

> Her mental processes are very unstable. Liable to hysterical attacks and aggressive towards patients at times. For this reason improvement of her spastic state by rehabilitation unlikely.

In the next two years she had two more outbursts of hysteria, and she was twice treated with antibiotics for respiratory tract infection. Short notes were made at three-monthly intervals up to her transfer to the West Middlesex Hospital.

On examination she was alert, rational, coöperative, and correctly oriented. Her memory for distant and recent events was good. There were no delusions or hallucinations. She was neat and tidy in appearance. The chest and abdomen were normal. The pulse was regular; there was a systolic murmur at the apex and splitting of heart-sounds at all areas; blood-pressure 140/80 mm. Hg; electrocardiography showed a right bundle-branch block. The skin of both lower legs was thin, pink, and shiny, and they became cyanosed on dependency. The left ankle was fixed in equinus deformity. Radiography showed a varus deformity of the left hip suggestive of congenital dislocation of the hip; the pelvis was asymmetrical, and there were osteoporotic changes in the left ankle. There was divergent strabismus with impaired vision of the right eye. Spastic weakness of the left arm and leg with a coarse flapping tremor of the left arm were present. Hæmoglobin 14.4 g. per 100 ml. (97%) and blood Wassermann reaction negative.

She was given clothes and was able to dress at once. Oversize shoes were put on her feet and she was soon able to walk between parallel bars. The orthopædic surgeon then performed a wedge tarsectomy of the left foot. The compression clamps were removed and a new plaster cast applied three weeks after the operation. She tried to walk with a crutch and holding a handrail but was handicapped by her weak incoördinate left arm. Two months after the operation she was given a walking plaster cast and soon could walk pushing a chair. She practised constantly by herself and refused unnecessary help if offered. When the cast was removed, surgical boots were fitted with a small heel raise on the left boot. She walked with a stick and went up and down stairs unaided. During her stay in hospital she was given new glasses, new dentures, and new clothes. She was interviewed by a welfare officer of the London County Council (since she was never a resident of Middlesex) and accepted by him on Feb. 28, 1955, for a welfare home in the vicinity of her old home. She thus returned after twenty years in hospital and thirty weeks of active treatment.

DISCUSSION

We have related this case-history not to elicit praise for any unit or therapeutic method, or to blame physicians for any lack of interest or treatment. The patient herself says she was treated with great kindness and the record shows no blemish. But we must criticise the negative therapeutic approach that cost the patient twenty years of freedom. Such an attitude is almost inevitable when patients are not seen until they have substantially lost their independence and have become bedfast. Only those who watch the decline from the first stages will appreciate the lost opportunities.

As this case-history shows, even review by a physician skilled in rehabilitation could not undo the psychological adhesions that bound the patient to bed. Yet all that was required finally was encouragement and a positive approach. Mistakes of this kind will not be avoided by the review of patients in chronic sick hospitals, but only by their repeated review in a long-stay annexe. Whenever possible the annexe should be an integral part of the unit to which they first appealed for help.

TREATMENT CENTRE FOR ALCOHOLICS IN A MENTAL HOSPITAL *

M M GLATT
M D Leipzig, D P M
SENIOR HOSPITAL MEDICAL OFFICER, WARLINGHAM PARK HOSPITAL, SURREY

IN 1948 in England and Wales the number of alcoholics with complications ("chronic alcoholics") was estimated at 86,000 (Jellinek 1951) This estimate was based on the percentage contribution of alcoholism to the number of deaths from liver cirrhosis Deaths from liver cirrhosis have risen from 816 in 1948 to 1155 in 1953 (Registrar-General 1949–54), and the W H O Alcoholism Subcommittee (1952) has suggested that this increase reflects an increase in the rate of alcoholism In view of the dearth of facilities in this country for the treatment of alcoholics (Dent 1952, Pullar Strecker 1952, 1955), the following description of a treatment programme evolved by trial and error at this public mental hospital may be of interest

The Start

Our first alcoholic group was formed in August, 1952, when four alcoholics happened to be in hospital at the same time These patients felt that they derived benefit from the group approach, and gradually the number of meetings and of alcoholic admissions increased To start with the group only met for an hour twice weekly, meetings are now held daily, and the male alcoholics form a closely knit, well organised group who live together in a ward, where they form at least half of the ward population, work together in occupational groups and usually also take recreation together (Glatt 1955)

The popularity of the group meetings in the hospital gave rise to the idea of forming similar groups for alcoholics after discharge and for outpatients At first there were not enough ex-patients to form such groups and there was no branch of Alcoholics Anonymous in our catchment area Our hospital group was therefore used as a nucleus to form a new A.A group at Croydon, which, with the help of the London service office of A.A , was started in November, 1952, and grew rapidly through the influx of non hospital alcoholics from the district All the Croydon A.A meetings, as well as those of other A A branches in the neighbourhood, have since been regularly attended by our hospital patients Two years ago they also formed their own A.A group in the hospital, and they hold open meetings every Sunday evening These meetings, as well as a Sunday afternoon meeting held by the social worker, give visiting relatives a chance to gain insight into the problem

Former patients have a standing invitation to attend hospital group meetings after discharge, and to keep in touch with ex patients who live in other parts of London Monthly reunions have been held in London for over a year Reports of these meetings are mailed regularly to all our alcoholic ex-patients, and have gradually expanded into a typewritten monthly magazine of 30–36 pages, now in its second year

Treatment

Sobering-up, detoxication, and physical building-up are no more than preliminary stages in the treatment of alcoholism Our long-term treatment programme for alcoholics is based on community living with other alcoholics, group therapy, close collaboration with A A., the use in some cases of drugs—such as disulfiram ('Antabuse') and apomorphine—as auxiliary weapons, and keeping in contact with patients after discharge

Community living and group therapy appear theoretically to be suitable means of treatment, for group activities seem to be a natural antithesis and antidote to personality traits often found in alcoholics, such as defiant individuality, grandiosity (Sillman 1948, Tiebout 1949), undersocialisation, and underparticipation in the activities of their surroundings (Bacon 1949) In a community and in groups formed by alcoholics who all speak the same language—enabling rapid identification with each other—each soon gets the feeling of belonging and learns to give up individualistic striving for the sake of sharing in the work for a common goal Each helps others by trying to help himself, and he gets encouragement to drop his façade and to reveal and face his real self when he sees others do it Often the alcoholic has been driven to drink because he felt unable to form human relationships without it, finally he has withdrawn more and more from society because of drink Community living and group activities help him in the process of resocialisation

In each patient alcoholism is probably due to severa causes, and no single form of therapy is suitable fo every patient A combination of several therapeutic methods selected according to the needs of each patien seems to be the most promising way of treatment Group therapy has been chosen here as the centra line of approach, for it makes the patient himself a active participant and is carried out with, and to a larg extent by, the patient himself and is not merely a therap meted out to him

The method used in the group discussions is in the mai a form of eclectic psychotherapy based on dynam concepts and a predominantly non directive approach Emotional reorientation and not mere intellectua understanding is the chief goal

Meetings are attended by doctors, the hospital chaplain —spiritual subjects often crop up at group meetings o alcoholics—and social workers, but they may also b held when no members of the staff are present

Aftercare

As the success of treatment of alcoholics rests largel on the standard of aftercare, we do our best to establis good contact and rapport with patients and their relative before discharge, and to anchor the patient firmly i A A On an average 10 patients—unaccompanied by hospital staff—visited outside A A meetings twice a week for over two years, and only rarely did any of them absent himself for a drink This may be partly due t the absence of responsibilities while in hospital, but i probably also due to the patients' acceptance of th code of their hospital group, whose ego ideal is not t

* Abridged from a paper read before the Society for the Study of Addiction on Jan 18, 1955

drink. After discharge the alcoholic will again meet people who are social drinkers; and to counter balance this influence, the importance of regular attendance at A.A. meetings and of maintaining contact with the hospital—through social workers reunion meetings, the monthly magazine &c —is strongly impressed on our patients.

The Patients

During the last two and a half years 150 alcohol addicts—i.e., alcoholics showing loss of control over their alcohol intake (Jellinek 1952)—were admitted to the hospital as voluntary patients Most of them were admitted because of social difficulties—e.g , continual loss of jobs or marital difficulties All had been heavy drinkers for many years and they were a rather hard core of alcoholics though on the whole not in bad physical shape. The ratio of males to females was 3·4/1 and most of them were in the age group 41–50 The majority of the men were of relatively high intelligence and belonged to the upper occupational groups (I and II) (Registrar General 1951) In several respects our patients are probably not a representative sample of alcoholics in this country

TABLE II—RESULTS OF TREATMENT IN 94 CASES TYPES OF IMPROVEMENT IN 77 CASES WITH KNOWN PRESENT STATE

Sex	Present state unknown	Present state known	Improvement (out of 7 cases) in:				
			Drinking	Work adjustment	Home adjustment	Social adjustment	Subjective feeling
Male	11	59	47	50	13	35	41
Female	6	18	14	8	16	11	11
Total	17	77	61	58	39	46	52

Dry or one relapse

Provisional Results

Alcoholism should not be considered to be ‘successfully arrested’ until abstinence has continued for at least two years (W H O Alcoholism Subcommittee 1951) Most of our patients have not been observed for as long as this. Tables I–IV can be no more than rough guides

77 patients have been observed for periods ranging from six months to two years after discharge from hospital.† Of these 77 39 had had no drink since discharge (‘recovered ’), and 22 had had no more than one relapse (‘improved) (table I) These patients had also improved in other ways (table II) 16 had had more than one relapse since discharge (not improved ’) but most of these were drinking less than formerly and their behaviour and general attitude had improved

In our material four factors seemed to affect prognosis men did better than women (table I) married people better than unmarried (table I), older people better than young (table III) and non psychopathic personalities much better than psychopaths (Henderson and Gillespie 1950) For psychopaths the prognosis is poor (table IV) though there is usually brief improvement The smaller proportion of psychopaths in the older age groups may largely explain the better prognosis of older alcoholics in our material The identification in the mind of the public of alcoholics in general with alcoholic psychopaths is probably largely responsible for many misconceptions

Discussion

Our alcoholic patients have been coöperative easy to handle, and by virtue of intelligence and initiative an asset to the hospital In setting up and running the group we have followed not any preconceived plan but a path of trial and error based on patients reactions to any proposed changes and innovations Despite the lack of planning and experience and the shortage of staff the only major difficulty that has arisen is our inability to admit many alcoholics referred to us

TABLE III—AGE DISTRIBUTION OF RECOVERED AND IMPROVED MALE PATIENTS

Age (yr)	Total	Improved or recovered	Not improved or unknown
21–35	10	4	6
36–50	38	25	13
51–66	22	18	4
Total	70	47	23

Similar schemes based on close collaboration of the mental hospital with A.A and on extensive group therapy, seem to deserve trial elsewhere If alcoholic patients were gathered in a few selected hospitals in each region instead of being admitted haphazardly to any hospital, groups could be formed in the selected hospitals and later in their neighbourhoods These in time would lead to the formation of new A.A branches all over the country and help to teach the public that alcoholism is an illness, lessen the stigma attached to it and encourage patients to seek treatment earlier

Many alcoholics can be helped by outpatient treatment or by A.A. alone but for some admission to a mental hospital may be a beneficial step (Rees and Glatt 1954) It may make clear to the patient how far drink has taken him induce in him a feeling of utter defeat and lead to a personality disruption ' and ego deflation which may be essential for successful treatment (Sargant 1949 Williams 1950 Tiebout 1954) No alcoholic can recover without a sincere desire to give up drinking, and daily contact in hospital with other alcoholics undergoing group therapy may sometimes induce this desire even in patients who entered hospital only to please wife or employer

Community living with other alcoholics rather than the official group psychotherapy sessions seems to be responsible for the change of heart and attitude which relatives often notice after only a few weeks This change of heart seems to begin more rapidly in men than in women perhaps partly because the women are fewer and lack the opportunity of living in a community of alcoholics though they attend the group meetings, which are mixed A mixed unit for alcoholics may therefore be of advantage; the feasibility of mixed units has been proved—e g in our unit for non-alcoholic neurotics (Martin Glatt and Weeks 1954) If patients could be admitted without statutory formalities (as in our neurosis unit) many alcoholics who are afraid of entering a mental hospital because of its stigma might find it easier to do so

TABLE IV—RESULTS IN NON PSYCHOPATHIC AND IN PSYCHOPATHIC MALE PATIENTS

Age (yr)	No of patients	Non psychopaths					Psychopaths

---

† In the six months since these tables were compiled there have been hardly any changes so the figures hold good for an observation period of one to two and a half years

Summary

A treatment centre for alcoholics at a public mental hospital, working in close collaboration with Alcoholics Anonymous, is described

It is suggested that alcoholic patients should be admitted to a few selected hospitals in each region, where they could form a nucleus for new branches of Alcoholics Anonymous in the neighbourhood

The establishment in mental hospitals of units for alcoholic patients—preferably of both sexes, with admission without statutory formalities—may prove useful for research as well as for treatment

I wish to thank Dr T P Rees, physician superintendent of the hospital, for his encouragement and his advice, the staff for their continual support, our social worker, Miss C Forrest, B A, for her laborious follow-up work, and the London service office of A A. for its keen coöperation

A CENTRE FOR CEREBRAL-PALSIED CHILDREN

CHILDREN are the concern of a great many people—the Ministry of Health, the Ministry of Education, the local authorities, voluntary agencies interested in special aspects of their welfare, and of course their parents, to name only a few To weld all these ministering angels into any kind of family party calls for resource and sagacity In the case of the new Centre for Spastic Children at 61, Cheyne Walk, Chelsea, London, these qualities were evidently at hand, for what has been achieved is a pioneer project, unique of its kind a voluntary centre launched within the National Health Service

It combines a medical centre with a school for children under 5, the school being under the London County Council, and the medical centre under the Chelsea group of hospitals Admiral J H Godfrey, who has been a moving spirit in founding the centre, is also chairman of the hospital management committee of this group, the centre's relations with its parent group are thus of the happiest The National Health Service, in Admiral Godfrey's judgment, has three serious gaps in its provisions for the very young, for the very old, and for pioneer projects In starting a pioneer project for the very young he has had the satisfaction of helping to stop two gaps at once

When the idea was first discussed, two and a half years ago, the South West Metropolitan Regional Hospital Board gave it their blessing—with a proviso that they were not to be asked to make any capital expenditure on it for three years In the event the whole cost—with the exception of the teachers' salaries and the school equipment, which are covered by the London County Council—has been borne by many donors, among whom King Edward's Hospital Fund for London is the chief, the William Johnston Yapp Trust, the London Parochial Charities, and an anonymous donor have also been particularly generous

The centre has its own medical committee consisting of Dr Ian Anderson, honorary director of the centre and consultant pædiatrician to the Westminster and St Stephen's Hospitals, Dr C D S Agassiz, late physician superintendent of Queen Mary's Hospital, Carshalton, Dr Francis Bach, consultant in physical medicine to the Chelsea group, Dr Anthony Feiling, consultant physician to St George's Hospital and the National Hospital for Nervous Diseases, and Dr John Foley, who is the consultant neurologist of the centre Mr Wylie McKissock, neurological surgeon to St George's and the National Hospital for Nervous Diseases, and Sir Harry Platt, president of the Royal College of Surgeons, have joined the committee as coöpted members

Dr Foley holds sessions at the centre at which he diagnoses the children's cases and advises on treatment His room at the centre is close to the records department and library, and next door to the filming room, in which permanent records can be made of the children's progress in walking and coordination The library contains a comprehensive selection of books bearing on cerebral palsy, which have been given by an active league of friends of the centre A file is also kept of all papers published on the subject, and it is hoped that this reference file will in time be so complete that it will be useful to all those working on cerebral palsy who care to consult it

TREATMENT

The centre, which is housed on the ground floor of the Cheyne Hospital for Children, has many comely, well lighted rooms, and these have been decorated with charm and distinction The white entrance hall, with its elegant thin touches of scarlet, lifts the spirits at once Wherever there are stairs a small scarlet handrail runs alongside, set at a level within reach of a small child. The centre takes for the whole day cerebral palsied children who are capable of benefiting by education in the school, and though it has only been open since the middle of April there are already 19 of them attending daily The plan is to add others, one at a time, until there are 24 attending daily, though it may be possible to increase the actual numbers on the strength by arranging for one group to attend on Mondays, Wednesdays, and Fridays and a different group on Tuesdays and Thursdays The number who can usefully attend daily is governed by the number of treatments that can be given the two keen young physiotherapists on the staff find that 12 treatments each are as many as they can complete in a day A few cerebral-palsied children who are not educable are being brought up daily for treatment of their physical condition These, of course, do not attend the school, and indeed they are spoken of as "outpatients" to distinguish them from the school children

The physical treatment room, warm, comfortable, and pleasantly gay, is equipped with two plinths and radiant heat lamps The physiotherapists have recently spent some weeks in Copenhagen studying Danish methods of treatment under Prof Preben Plum at the Rigshospitalet They make good use of ultraviolet light, hot and cold sprays, and massage, including vibration and shaking of the muscles These simple methods, they find, improve the circulation in the blue limbs of these children, and help the muscles to relax

A speech therapist attends twice a week and has her own treatment room where she can give speech training and take records of the children's speech for reference and comparison The tape-recorder in her room has an extension in the corridor outside, so that those interested in a child's progress can listen without interrupting the session They can also watch the child (without themselves being seen) through a darkened glass panel in the door

EQUIPMENT

The well-made furniture of the classrooms and the children's dining room is of a size to suit their age

The centre has the services of a skilled hospital carpenter, a tall upstanding man of 75 who sees no reason for retiring, and who, besides making much of the furniture carries out any adjustments needed to chairs and foot rests, and executes, with beautiful fidelity, any new designs brought to him

The wash basins and water-closets in the children's lavatory are also on an appropriate scale and there is a wooden chair-frame with arms but no seat, which stands over the lavatory pan and enables the child to pull himself up when he rises The wash basins have lever handles to the taps which the children are able to turn on and off more easily than they are the screw type Two competent house mothers look after the needs of the children, prepare them for treatment, and supervise meals

At present there is only one large classroom, its glass doors opening on to a little tiled terrace where classes can be held on sunny days The doors have been specially designed so that they will not shut to of their own accord and perhaps trap fingers An important piece of equipment in the school room is the piano for rhythmic games are useful in helping to establish control of muscles Outside, in a pretty little garden a new classroom is going up, modern in design with windows all along one side The garden overlooks another garden—that of Chelsea Old Church, now rising again from its wartime ruins and the keen gardeners among the congregation, who keep the church grounds in flower, are also going to lend a hand with the centre's garden At the bottom of the building is a yard with a perambulator garage but some ideas are already stirring about the centre's own van—or perhaps two vans—to be driven by volunteers who would go round collecting the children in the morning and delivering them back at their own doors in the afternoon

The most striking thing about this centre is its happy atmosphere The affectionate kindness with which these intelligent handicapped children are treated and taught is a final expression of the whole spirit of the place

REGIONAL HOSPITAL BOARDS AND BOARDS OF GOVERNORS OF TEACHING HOSPITALS

THE Minister of Health has reappointed the following as chairmen of boards

Newcastle Regional Hospital Board —Edward F Collingwood, C.B.E., D.S.C J.P

United Manchester Hospitals —N M Agnew

Bethlem Royal and Maudsley Hospitals —Mrs. F C Ormerod.

Hospital for Diseases of the Chest —Widdrington Stafford.

Queen Charlotte's and Chelsea Hospitals —A J Espley C.B.E., J.P

The Hospital for Sick Children —Claude A. Lucas T.D M.A LL.A.

Eastman Dental Hospital —A. D Page

MEMBERS OF BOARDS OF GOVERNORS

The following doctors have been appointed to boards They will hold office till March 31 1958 New appointments are indicated with an asterisk.

St Bartholomew's Hospital —F C W Capps, Sir James Paterson Ross.

London Hospital —H. B May J Stanley Thomas Vernon Thompson, Eustace Hoare Clifford Wilson.

Royal Free Hospital —Geraldine Barry G E Breen D H. Geffen, J C R Hindenach * J S F Pollitzer

University College Hospital —Cecil Flemming, J D S Flew K L. Harris S Cochrane Shanks.

Middlesex Hospital —* W R Winterton.

Charing Cross Hospital —Norman Lake, * A Doyne Bell * Lionel Taylor

St. George's Hospital.—Sir Claude Frankau, Hugh Gainsborough, Alastair Hunter D Stark Murray * H H D Sutherland (till March 31 1956)

Westminster Hospital —F D Hart

St Mary's Hospital —Joel Green, * J W Litchfield * F W M. Pratt

Guy's Hospital —E. R Boland, A. Talbot Rogers, E G Slesinger * A. H. Douthwaite * Grant Massie

King's College Hospital.—F S Cooksey, Sir William Gilliatt, V F Hall, J H. Peel.

St Thomas's Hospital —W G Barnard, J Forest Smith, C H Vernon, R H O B Robinson, * R W Nevin.

Hammersmith West London and St Mark's Hospitals —John McMichael Charles Newman, Maurice Shaw

The Hospital for Sick Children —A P Norman Wilfrid Sheldon

National Hospitals for Nervous Diseases —Sir Francis Walshe * Redvers Ironside * Alan Kekwick.

Royal National Throat, Nose and Ear Hospital.—Adam Gray C Gill Carey * J W Cope

Moorfields Westminster and Central Eye Hospital —R. C. Davenport, Sir Stewart Duke Elder * Cyril Shapland.

Bethlem Royal and Maudsley Hospitals —Sir Allen Daley D L. Davies, A. Harris, Doris Odlum, F R Winton

St John's Hospital for Diseases of the Skin —R M. B MacKenna, J E M Wigley

Hospitals for Diseases of the Chest —Sir Clement Price Thomas, J G Scadding J Smart * Sir Geoffrey Todd.

Royal National Orthopaedic Hospital —H Jackson Burrows John Cholmeley

National Heart Hospital —Graham Hayward G H Jennings P H. Wood

St Peter's St Paul's and St Philip's Hospitals —Clifford Morson J G Sandrey

Royal Marsden Hospital —Sir Stanford Cade D W Smithers, Alexander Haddow (till March 31 1957) * W A Mill.

Queen Charlotte's and Chelsea Hospitals —S G Clayton, Charles Read * Humphrey Arthure (till March 31 1957)

Eastman Dental Hospital —Frank Wilkinson * R R Stephens

BIRTHDAY HONOURS

THE *list appearing in our last issue omitted the names* of two members of our profession on whom honours have been conferred They are:

O B E (Military)

Wing Commander LILIAN GERTRUDE MOORE M B Belf., M.R.C P.E R.A.F

Wing Commander JAMES CLARKE TAYLOR, M.B Glasg R.A.F

NEW MATERNITY HOSPITAL IN CARDIFF

THE steel skeleton of a new maternity hospital stood beside the Cardiff Royal Infirmary throughout the war years. On the outbreak of war in 1939 building was discontinued and it was not until May of this year that the hospital admitted its first patients. The hospital, which is administered by the board of governors of the United Cardiff Hospitals, has its *own matron and is a part-I training-school for midwives.*

Of the six floors the top two are devoted to nurses quarters but they have been so designed that they could readily be converted to take patients. On the ground floor are antenatal and baby clinics, X ray department lecture-theatre demonstration room library kitchens, administrative offices and the clinical research laboratories of the department of obstetrics of the Welsh National School of Medicine The patients are accommodated on the remaining three floors. Each floor has 27 beds and, apart from minor variations in the nursery arrangements, they form identical units consisting of delivery suite of two first-stage rooms and two delivery rooms nurseries, five 4 bed bays, and seven single rooms. On one of the floors is a premature baby unit, and on the same floor one of the delivery rooms is equipped as an operating theatre

The babies will ordinarily be nursed with their mothers, but there is enough nursery space to accommodate all the babies at night. Continuity of nursing care for the mother will be ensured by having the same staff in charge of antenatal beds delivery room, lying in beds, and nursery for normal babies Anæsthetic gases are piped to the delivery rooms and oxygen and suction points are provided in the wards. Sterile water is laid on and elaborate antistatic precautions have been taken in constructing rooms in which anæsthetics may be given

The new hospital is to be officially opened on July 12 by the Duchess of Kent.

The Widdicombe File

XXVI THE HOUR OF THE ANGEL

Dear Charles,

I'm exceedingly glad to hear you can take our rooms at Mrs. Woof's in August. Rooms on the Devon coast in August at six guineas a head are not to be sneezed at ever, and hers are worth double. She will look after you and the family admirably. Wychecombe Bay itself is overrun now by caravan camps (the hills around have been terraced for caravans till they look like the work of Ancient Britons in Somerset), but Wattecove a mile away is just as good, and deserted because it has no motor road.

Let me tell you though before you go, as an awful warning, of a thing which happened last year. Did you ever have to resuscitate the Apparently Drowned? I did, and it was not a pleasant experience.

It was, you remember, an August of lousy weather last year, and the day in question, though rainless and almost warm, boasted about five eighths of an onshore gale. Beatrice and I, very much *en famille*, came over the cliff path into Wychecombe Bay towards lunch-time, intending to buy apples at the caravan camp shop. As we came in sight of the beach we could see two most ominous looking huddles of people at the water's edge. There was a man leaning over the end of a stone wall, watching them through field glasses. “ No, it's nothing,” he said. “ Rowing boat brought something ashore—fish, I expect.” Reassured, we yet urged our litter a little faster downhill. Halfway down, five wasted minutes later, I began to doubt the diagnosis of the fool with the field glasses, and soon was running as hard as I could across the wide wet sands. The two huddles meant two bodies, and they had been pulled out of the sea just before we caught sight of the beach.

There were a lot of people on the beach, and I had some difficulty in getting to the centre of the first knot. There lay there a heavily built, thick-necked man of 40 odd. He lay on his face on the wet sand, with two towels and a raincoat over him but nothing under him. One of the rescuers was applying artificial respiration (Schafer's method, more or less) at about 60 to the minute. Seven others at least were rubbing his limbs violently. No one was paying any attention to his airway. Two stout gentlemen were contesting who could shout “ stand back, give him air ” most importantly, though the close ring of onlookers was in fact our only shelter against the wind. There were all the makings of farce, except the happy ending.

He was pale and cold and bluish round the ears, but looked, to my inexpert eye, extremely alive. I said, loud as I could, “ I'm a doctor. Who's in charge here?” The assembled company looked at each other, but admitted no leader. They looked then at me, and found in my ancient ski jacket, torn shorts, bare legs, broken sandshoes, and peeling nose little to reassure them. This, they thought, could hardly be a *proper* doctor. The feet nearest the patient's head were reluctantly moved away enough to allow me to kneel down by him. I felt a doubtful carotid pulse, manœuvred the head into a position rather more compatible with a free airway, and attempted to take stock. You must remember at this point that I had never dealt with drowning before, that my last clinical responsibilities had ended shortly after V.J.-day, that this case came out of the blue of a holiday which was family ridden and rain soaked but otherwise completely placid, and that I had only the moments of my run across the beach to recondition me to this most unfamiliar emergency. There were two problems: what to do, and how to get someone to do it while I went to look at the other body.

At this moment a heave in the crowd brought up a blank faced young woman, with a chorus of “ She's a nurse, doctor.” She remained dumb, but took over the head with some appearance of knowing what she was doing. I exhorted the artificial respirator to slow down his rate, and told the nurse to keep him at it, and escaped, thankfully I'm afraid, to survey my second problem.

At the centre of the second huddle, in most respects just like the first, was a boy of 13 or so. His nose was nearly buried in the sand, and vigorous artificial respiration was being applied. All appearances to the contrary however, his airway was clear, and indeed as I turned his head the air could be heard bubbling quietly in the larynx with each heave of the resuscitator's body. The resuscitator was himself panting with his efforts, and I suggested he slowed down a little. This was received with no favour: clearly he considered that the harder he worked, the more good he must be doing. But I persuaded him to stop a moment while we got some towels under the body, and in that moment the body had the wit to produce a faint gasp of spontaneous respiration. We waited, breathless ourselves, for half a lifetime—thirty seconds I suppose—and it was repeated. Here at least was one success.

Obviously what he needed was assistance to deepen each spontaneous breath, and the two of us worked at the timing of it for a minute or two. It looked better and better. One would have supposed that our exhilaration would have equally possessed the onlookers. But no, survival was an anticlimax, and the circle was thinning. The wind whipped in again, and I wasted another minute or two in expostulation before anyone would hurry up the beach to speed the stretcher which it was vaguely assumed that someone was fetching. The huddle of bowed heads round the other body showed there was no such success yet in that quarter.

I elbowed my way back into the centre. The nurse had vanished—how or why I never discovered (she cannot, I think, have been a real nurse—perhaps a nurse maid misidentified and too overwhelmed to disclaim it). There was a veiledly acrimonious dispute going on over the resuscitation roster (“ Old man, you've had enough now, you're tired ”) and the rate was still around 60. The body looked much the same, but by contrast with the one I had just left looked much more dead than it had before. I could not feel the carotids. The resuscitators proved incorrigible in their adherence to an excessively rapid rate, and I decided (reluctantly, for it lost me my freedom of movement) to resolve their arguments by taking over myself. The body was cold and wet as I straddled it, and the fat muscular chest ominously stiff as I leaned forward on it with straight arms and ostentatious slowness. I had time at least, for the first time since reaching the beach, to begin to wonder where we went from here. The ring of staring faces remained as blankly unhelpful as the casual urban audience of a hole in the road. The tide began to lap round their ankles: we would soon, willy-nilly, have to move.

Blessedly at this point the matter was taken out of my hands. Simultaneously there arrived the local G.P., a St. John's man, and the police. The police (sixteen stones of him) brought a van and a stretcher, the St. John's man experience of these affairs beyond mine, and the G.P. not only knowledge and experience but the dress, bearing, and bag of a real doctor.

After that all went as it should in the books, and there's not much point in continuing. The boy was soon mended, the man proved to be beyond recall. Harry Hawke did the ys for the coroner and the coroner told us how unwise is to bathe in even the safest of West Country bays when the tide is low and the wind high And that was that Perhaps the three prosperous little caravan camps who live on the bay have provided a stretcher between them this year and got one of their staff trained in resuscitation or perhaps they've forgotten It might be an idea if you inquired—tactfully

For myself I am still more than a little harrowed by the memory Probably what I thought was a carotid pulse when I first saw the man was an illusion—my own rapid pulse from running even a transmitted pulse from the persistent massage school on the legs But I will never be certain, and never be quite certain that we could not have saved him

That damned ignorant staring helpless crowd still haunts me

> I know not whether I am proud
> But this I know I hate that crowd.

Not one man or woman in that sample of 200 or so of the prosperous lower middle classes of England knew a thing about first aid for the drowning beyond the barest notions of Schafer's method No one had any notion of organising the crowd and assuming some sort of responsibility One wartime sergeant of gunners remembering something of his authority, and a few fuglemen to give a lead in *following him would have made all the difference*. By the time I arrived on the scene the mob was lost disheartened convinced of its own futility and the futility of any further effort, passively panic-stricken

Not that I'm very happy about my own part in the affair I did most of the right things (barring the Holger Nielsen which I didn't know at all) but I had to work them out from first principles and wasted time and thought getting started on them I neither looked like a doctor *nor* acted with the instantaneous decision expected of one and lost the moment of confidence in which I might have imposed myself on the mob as the needed boss.

You and I, Charles have retired so far as our jobs are concerned from the life and death responsibilities of clinical medicine into our laboratories We may have major decisions to make but we make them quietly in our own place and almost in our own time We do not have to make them with a thumb on the artery in the theatre or blanching under the stench of vomit in a crowded basement bedroom We keep our side of the bargain we work under laboratory conditions, and we accept the responsibility for producing results of a laboratory standard of accuracy But outside our working hours at the roadside or on holiday by hill or river or sea the accident catches us unawares, without our defensive armour of forms and bottles and reports housemen and secretaries and technicians and we are plain doctors again, with a life nakedly in our hands to save or lose. It is Ithuriel's hour—

> the test
> Of our sole unbacked competence and power
> Up to the limits of our years and dower
> Of judgment—or beyond.

I don't seem to have come out of my hour with the angel more than middling It boils down to this though the gift of confident authority comes of knowing what to do. There are occasions when even the illusion of knowledge is better than nothing at all I know that if ever again I encounter a similar situation I will blow out my chest screw up my courage tick off the biggest man in sight at once and act not merely the good doctor but people's idea of how a good doctor should act But it's much easier if one knows what one's up to

Do you know as much first aid as a moderately good St John's man Charles? Disgracefully few pathologists do Come to think of it 50% of the profession are probably just as bad We like to be called "Doctor" we accept our little perks like the occasional chemist's discount no jury duty, and side wards in hospital for us and our families we do not even question the G M C's view *that the man who qualifies must already be capable* of the basic responsibilities of a doctor But emergency not so rarely shows us barely worthy of our honourable title

You'll enjoy Mrs Woof's Charles But read up a few first aid manuals before you go and make sure you know the Holger Neilsen I need hardly say I have

Yours
PETER DAVEY

PS —I've just seen an excellent little book from New Zealand called *Artificial Respiration* by T O Garland (Faber & Faber 6s 6*d*)—the best I know of so far

Public Health

Uses of Radioactive Waste

WORK on radioactive waste in the United States and at Harwell suggests that many medical and industrial uses can be found for it, and a new research group has been established at Harwell to investigate the possibilities.[1]

One line of research will deal with the preservation of food by exposing it to irradiation from waste. It is possible that the widespread use of radiation sterilisation may reduce, or perhaps even abolish, the need for refrigeration to keep food fresh For example, the Royal Navy is already being supplied from Harwell with potatoes that have been treated so that they will not sprout In America it has been found that when meat is irradiated so that it keeps indefinitely it has a different taste—though the taste is normal if the meat is only partly treated to preserve it for shorter periods. Full scale experiments will begin at Harwell this year and it is hoped to solve the problem of taste within two years. Dr H Seligman, head of the isotopes division at Harwell has said that the main concentration of British food experiments may consist of attempts to improve the "shelf life" of food rather than to preserve it indefinitely, tomatoes, for example, can be made to last fifteen days on a shelf before going squashy rather than five days as now It will also be possible to treat food before it is packed

Radiation from waste can also be used to speed up chemical processes, such as the preparation of gammexane; and there are many possibilities in the manufacture of expensive drugs such as hormones The sterilisation of pharmaceuticals is another application and this will be particularly valuable where heat cannot be used as with penicillin and streptomycin As for radiotherapy the most successful fission product seems to be cæsium 137 and radiation from large sources of *cæsium may turn out to be the most satisfactory method* of radiotherapy so far evolved

In industrial processes, it has been found that irradiation makes 'Polythene' more resistant to heat so that cables can be used at higher ratings and temperatures. Vulcanising processes can be speeded up and the application of irradiation in oil refining is being further investigated.

Poliomyelitis in Barnsley

There have been 22 confirmed cases of poliomyelitis in the Barnsley area of Yorkshire The medical officer of Health Dr G A W Neill has said that the outbreak is not a serious one,[2] but the usual administrative precautions have been taken including the stopping in schools of pursuits likely to cause physical fatigue

2. *Manchester Guardian* June 20 1955

Parliament

Future of the Social Services

THE fourth day of the debate on the Address (June 14) was reserved for a discussion of the social services Dr **EDITH SUMMERSKILL** opened the debate by regretting that the Queen's Speech contained not one word on the sick and the aged She went on to ask the Minister of Health how many new beds would be provided this year for our mental hospitals, how he proposed to recruit extra staff for these hospitals and the sanatoriums, and to provide, through the local authorities, home helps and halfway homes for old people

She also regretted that the recommendations of the Gowers report were apparently to be so tardily implemented The Gracious Speech announced that a Bill was to be introduced on the health, welfare, and safety of those employed in agriculture and forestry, but no mention was made of workers in shops and offices and on the railways Turning to the services under the Ministry of Pensions, Dr Summerskill declared that the pigeon-holing of the Phillips report was not only discourteous to a distinguished committee but showed a callous disregard for the needs of the aged She also asked whether the proposed extension of family allowances would include children at all colleges, and also mentally retarded children who remained dependent on their parents

Mr **OSBERT PEAKE** Minister of Pensions and National Insurance, defended the priority given to the Bill for the protection of workers in agriculture and forestry on the grounds that these industries were becoming ever more mechanised and the accident-rates had risen If there were time a Bill dealing with safety and health on the railways would also be presented The Bill dealing with shops and offices would be much the biggest Almost certainly it would be impossible to introduce it in the first session The Government had in mind that the age-limit for family allowances should be 18 After all, the scheme was in respect of children, and to go on counting people as children after they had qualified for National Service would seem to be going rather far Some provision would be made for handicapped children

As a result of the changes recently made in the pensions scales of benefit, he continued, about 111,000 fewer people were drawing assistance today than 2½ years ago There was every sign that we could look forward to a steady reduction, and he believed that we might approach the Beveridge idea of a society in which the means test was hardly ever exercised Much had already been done to rebuild our social services The value of pensions and benefits, which 3½ years ago had steadily fallen was now fully restored and provided better purchasing power than ever before There was still much to do In the first session of this new Parliament the main emphasis would be on education and housing, but the Government believed that, given freedom from industrial disputes, given a reasonably steady cost of living and increased productivity, the beneficiaries of the social services could look forward to a better future

Miss **EDITH PITT** thought that we were getting good value for the £463 million we spent on the health service, but she believed that we could get even better value if we concentrated on preventive work She would like to see more emphasis on the use of the family doctor Since the 1953 award he was better paid, but he still had too little time to pay full attention to every member of the family Sir **FREDERICK MESSER** was troubled because we seemed to be separating health from welfare, and this in his view was a big mistake The lack of integration was particularly marked in the welfare of the aged

Mr **J K VAUGHAN-MORGAN** saw an increase in domiciliary services as a first line of defence in health, and he hoped that the reform of local government forecast in the Gracious Speech would include some means of closer association between the local authorities and the health services He recalled that when the Ministry of Health was founded in 1919 it was given the positive duty of "promoting the health of the people" Since then its powers had been whittled away until its main preoccupation was curing ill health rather than preventing it Many of its duties had been reshuffled to the Ministry of Local Government and Housing He would like to see the industrial health services transferred to the Ministry of Health The expected report of the Guillebaud Committee and the promised reform of local government would, in his view, give us a chance to rebuild the National Health Service on a sounder basis

PAYING FOR SECURITY

Miss **ELAINE BURTON** suggested that in this century we had established the principle that the community must provide social services for its citizens In the years to come she hoped that we would develop the services with the aim that they should be given to a citizen as a right, without test of means To achieve this money could be provided in three ways by graduated contributions, by a social security tax, or out of general taxation In her view it was wrong in this modern age that social services should be paid for by all citizens at the same rate, irrespective of what they earn

Mr **DOUGLAS HOUGHTON** also examined the basic aims of social security today Are we prepared, he asked, any longer to think of Beveridge minimum subsistence pensions? Were we not to think now in bolder terms of the construction of a cost-of-living index for old people The standard pension for married couples was now only a third of the average wage That was not adequate social provision for retirement We must, he suggested, look at our scheme of social security more as a national superannuation scheme than as an insurance scheme

Mr **JAMES GRIFFITHS** described the flat-rate contribution as "the most aggressive tax we have" The only person who now paid the full insurance contribution was the one who did not earn enough to pay income-tax Unless a fundamental change was made in our system of social insurance, National Assistance would become increasingly, not a residual service, but an integral part of our welfare system

THE MINISTER'S REPLY

Mr **IAIN MACLEOD**, the Minister of Health, pointed out that the Queen's Speech covered only one aspect of the programme which the Government had outlined in their policy statement Of the subjects affecting his Ministry the only promise of legislation was for medical auxiliaries He did not think it was likely that that legislation would be ready for this session, although considerable progress had been made

Schemes already approved and in current building programmes for England and Wales would provide 7000 new mental-deficiency beds and there were under consideration schemes which would provide at least another 2000 1000 extra beds had been provided in mental hospitals since 1948 Beyond that, 3000 had been approved in the current programme and proposals for another 500 were being considered The staff deficiency on the mental side might be estimated at about 10,000, though the nursing staff as a whole had been slightly increasing year by year The home-help service had gone up from 11 000 at the end of 1948 to over 33,000 at the end of 1954 In the last year 62% of the cases looked after by home helps were classified as chronic sick There was no absolute duty under the National Health Service Acts to provide this service, but all local authorities provided it Some time this year—probably in the autumn—the Government would receive a report from the Guillebaud Committee The review and any reconstruction in the National Health Service that would follow would be carried out by the present Government

The social services ought now to be breaking clear of their teething troubles It should be possible to find some principles which should guide them in the period ahead First, he thought that increasingly responsibility should go where the work was done That would mean of course a trend in responsibility downwards, and this was one of the matters which were being considered by the Ministers concerned with local government Secondly, he thought they should try to bind together more closely in comradeship the voluntary and the State services.

They should try to get leagues of friends increasingly active in the hospitals, and the hospitals should be more open than they were now People should begin to feel that they owned the hospitals The third and last principle was that they should try to encourage diversity in the social services. In the health service people should not be prevented from buying privacy for themselves or their families when they were ill. He did not believe that any single pattern could cover the range of the social services and it was therefore of great importance that they should encourage independence in every possible way Finally it had to be remembered that the social services had to be earned and paid for by the prosperity of the country they were not a gift of Government.

QUESTION TIME

Poliomyelitis Research in Scotland

Replying to a question Mr James Stuart secretary of State for Scotland, said that the Scottish Hospital Endowments Research Trust had accepted the first application for financial assistance for research into poliomyelitis and other virus diseases. This consisted of a grant of £3000 to meet the cost of equipment which would be required shortly in the new virus laboratory at Ruchill Hospital, Glasgow

Crash Helmets

Mr Barnett Janner asked the Chancellor of the Exchequer whether he would consider taking steps to remove purchase tax from crash helmets, in view of the recent recommendation of the British Medical Association and the fact that some [illegible] million a year is involved in treating people in hospitals who are unable to afford to buy this article —Mr R A Butler replied This is a matter which I have considered very carefully in view of the representations made to me but I am not yet convinced that motor cyclists are deterred from using these articles by the few shillings tax involved Mr. Janner Is not the Minister aware that some 1300 deaths a year are caused by these helmets not being worn ? Even if the persons themselves are not prepared to purchase the helmets, does he not think it the duty of the State to afford facilities for those helmets to be used ?—Mr Butler : I hope that people will wear these helmets but I am not at present in a position to remove the tax

Sir Frank Medlicott : Will the Minister bear in mind that purchase tax was originally imposed partly to discourage people from buying things ? Is it not time that we removed this particular discouragement from this very valuable and life-saving article ?—Mr Butler There are other forms of important protective clothing which are still taxed, and I am afraid that I cannot go further in my answer today

Myxomatosis

Replying to a question, Mr Heathcoat Amory Minister of Agriculture said that his department had examined surviving rabbits from many parts of the country and of these 39—or about 10%—were found to have acquired immunity to myxomatosis. It was not however possible to say whether this proportion was representative for the country as a whole Mr Somerville Hastings Is there any evidence that this immunity is carried to the next generation ?—Mr Amory : I understand not, except possibly for the first few weeks of a young rabbit s life

Heroin Addiction

Replying to a question Major Gwilym Lloyd George Home Secretary said 52 heroin addicts are known in England and Wales and 2 in Scotland. At the present time there are no persons in respect of whom addiction is suspected but not proved Drug addiction is not compulsorily notifiable in this country but I have no ground for thinking that there is any substantial hidden addiction From Jan. 1 1950 to date 23 persons were convicted in respect of 24 offences involving heroin, one person having been convicted twice Of these 23 persons, 15 are known heroin addicts and 1 person who has since left the country was suspected to be addicted to the drug

Prices of Drugs

Replying to a question, Mr Iain Macleod said that since May 1953 of the 73 most expensive and frequently prescribed proprietary preparations, 29 had been reduced in price (many between 20% and 60%) some of these reductions reflecting in part reductions in the basic drug prices. In addition special provisional reductions ranging up to 20% were recently arranged with manufacturers in the prices of 19 proprietary preparations During the same period the prices of certain important basic drugs and their corresponding products had been reduced some of them several times. These voluntary reductions included some recent ones (since June 1954) ranging up to 20% in the prices of penicillin streptomycin chloramphenicol and hormone and vitamin products

Poliomyelitis Vaccine

Replying to a question, Mr Macleod said that a member of the staff of the Medical Research Council had just returned from a visit to the United States where he had been studying the latest developments regarding anti poliomyelitis vaccine No explanation for the Cutter vaccine incident had yet been found but it was possible that certain batches contained live virus He understood that the safety tests to be applied to the vaccine in the United States had been greatly multiplied, including a closer control of manufacturing processes. Pending the introduction and application of similar measures here, the Medical Research Council had postponed the start of any field trials This would probably involve a postponement until the late autumn of this year

A Doctor and the Rail Strike

Mr James Baird asked *the Minister of Health* what position under the National Health Service was held by the doctor who declined to see one of his patients, the wife of a railway striker until the strike was over —Mr Macleod replied that the doctor was a part-time consultant to the board of governors of the United Birmingham Hospitals and to the Birmingham Regional Hospital Board

Mr Baird : Was the doctor s action not completely unethical and did it not amount to political discrimination ? Will the Minister see either that the doctor changes his principles, or that his name is withdrawn from the National Health Services list ?—Mr Macleod : If there were any question of breach of contract within the National Health Service it would be a matter for which I would be glad to answer but if it is a question of medical etiquette which the hon member seems to raise that is not for me nor is the matter of a private arrangement which a doctor might make with his private patient Mr Baird : Is it not a fact that this doctor says that his principles do not allow him to see these people ? Surely his principles must operate in the National Health Service as a whole and what he is saying is that he will never see a patient on strike ?—Mr Macleod Equally there is a matter of principle involved in my reply I cannot reply on matters for which there is no Ministerial responsibility at all, and that I am afraid, is the case in this regard

Criminal Offences by Mental Defectives

Mr Kenneth Robinson asked the Minister of Health why under circular H.M (55)46 he required the police to be informed of sexual acts by certified mental defectives, in addition to the normal report to the Board of Control whether he was aware that medical superintendents had been informed by his department that such reports to the police were still discretionary ; and if he would revert to the earlier procedure by withdrawing the circular —Mr Macleod replied : The circular was issued after consultation with the Home Secretary because the earlier procedure which had only been in force since 1951 did not have sufficient regard to the duty of the police to investigate criminal offences. The circular advises but does not require cases to be reported to the police I am aware of no good reasons for its withdrawal

Mr Robinson Surely the Minister is not suggesting that the police should prosecute in cases like this ? Is it not a fact that the old arrangements have been working quite satisfactorily ? Why does the Minister want to place this additional burden on medical superintendents ?—Mr Macleod There are certain cases which by the 1913 Act are in effect criminal offences which come within the terms of the circular We are getting back to the practice which operated before 1951 This is a matter of doctor patient relationship and the final decision of whether the police should be notified is left to the medical superintendent

In England Now

A Running Commentary by Peripatetic Correspondents

FOR the past five weeks I have been lying in bed healing a duodenal ulcer. For most of the time I have been in my bed at home looking out on what is to me one of the pleasantest views in England. The foreground is a field, with cows in it, sloping gently to the village a quarter of a mile away. The village is—just an English village. It is not one of the show places, and no circular tours call there; but it has a nice old church, just in the right place, and houses of every period living happily together. There is a little river at the foot of the hill and the backcloth is a low range of tree covered hills. It all looks as though it had been there a very long time.

While I have been in bed the scene has shed its winter mantle and put on its early summer one. At first the trees were bare and at the end they were clothed in the lush green of summer in the West Country.

Then I developed a small complication and the friend who was looking after me decided that I must go into hospital for a short course of treatment; nothing drastic but something with plenty of needles in it.

The hospital has a long and honourable tradition, and like our village it has just growed over the years. My guest room is tucked away in a small building in the back yard of the main one—called, rather inappropriately, the "Cottage"—and the rest of the back yard is filled with a hotchpotch of buildings of every shape and size which epitomise the history of medicine in the last two hundred years or so. I am afraid that, unlike our village, they are not beautiful. The "Cottage" is one of the early ones and was built as an isolation block at a time when it must have been badly needed. Its internal decoration is Doulton unadorned, with glazed white tiles from floor to ceiling, and it must have been the pride and joy of some long dead apostle of hygiene. However, between me and the hideous back of the "new" X-ray department there is a garden. It is none of your sooty urban flower beds, but a real garden, with a real tree, in which the birds sing just as sweetly as they do in my garden at home. When I admired it Sister said "Oh, but you should have seen it last week when the tulips were at their best." Sooner or later I expect the cottage will be pulled down to make room for the new department for cosmic ray treatment or some such. I hope that the "cottage" garden will not have to go too.

* * *

I cannot honestly say that I appreciate the modern composers or the twelve-tone system which the pundits talk about. However, I confess that I was rather put out by the cat the other day. She was sitting quietly washing herself when suddenly she perked up at the sound of Hindemith. She strolled over to the radio, quite casually, and sat down to listen until the end of the concert piece and then returned to her basket and her toilet. It is disconcerting to be outclassed by one's own cat. I now blush at my staple diet of Mozart and Beethoven.

Have you ever noticed how little difference there is between babies and small animals? My cat's love of Hindemith reminds me of a friend's experience lately. He and his wife had moved temporarily into a hotel, taking with them nothing but the bare essentials and, of course, the baby. The child, aged eighteen months, was completely frustrated all day and most of the night. It defied three grains of chloral. It became semi-comatosed on five grains only to awaken two hours later as noisy and as troublesome as ever. And all because it missed its music. It was happy only while stamping around the floor or beating the side of the cot with a metal spoon in time with the music. My friend had to bring the family radiogram to the hotel. The latest report from the distracted father was that anyway it showed a growing appreciation of Bach.

Now this you will realise was no mean feat. In a matter of months this child had completed what the experts aptly call "the musical pilgrimage" which (they say) starts with Chopin and Liszt and ends with Bach. Surely in this day and age with Three Blind Mice, Little Bo-peep, later with Men of Harlech, later still with the Lord High Executioner, we are handing out inferior stuff for the all-impressionable, all-embracing minds of our offspring. The time has come when Listen with Mater should be Listen to Mahler. By five years of age our children will surely be ready to benefit by The Exposition of the Fugue for Five-year Olds, the Contrapuntal Element in the Classics for Children, or even Tchaikovsky for Toddlers.

* * *

What Samuel Pepys called his "House of Office"—which was a source of offence between him and his neighbours—was in my boyhood called a "W.C." The term indicated the change in domestic life wrought by the introduction of an abundant piped water supply and the disappearance of the well. A water, as opposed to an earth, closet was something of a novelty—such as "H and C" is occasionally today. Victorian England refined the water-closet into the "W.C.," though in rather unsophisticated circles—as it seemed to me, across this span of time—the rather *démodé* word "closet" was sometimes used alone. In family circles the "W.C." was apt to be abbreviated to the "W." The insidious ingression of Americanisms (is it not indelicate to talk of the breast of a chicken; and does not your hostess ask you if you prefer a "limb" or "the chest"?—unless maybe the deep-frozen animal is now purveyed in "portions") ousted the "W.C.," abetted in this by material progress, and gave us the "lavatory" which today has become the "toilet." International air-travel has guilded this sophistication and air hostesses tell us that "the ladies' powder room is at the back of the plane on the right hand side" (meaning on the starboard side aft). Our Georgian ancestors, or some of them, had "powder closets," and it is a nice speculation whether the "powder room" will revert to the old form, and full circle bring us back to the "closet." But terminology advances along strange paths, so that in a recent visit to the Western Hemisphere all I could find offered for man's, or woman's, need were "rest rooms." I didn't want to rest and, finding no alternative label, vaguely wondered if in some obscure annexe of that doubtless commodious apartment there might be the facilities required. I entered, and found merely a W.C.! *Plus ça change* . . .

* * *

She was a motherly old body, but her symptoms seemed to be functional, so the psychiatrist's aid was sought. He interviewed her in the ward side-room, and some time later the sister asked her how she had got on. She had apparently enjoyed her chat, had thought the doctor was a nice young man, but was sorry to find him so restless, and smoking so many cigarettes one after the other. She really felt it would do him good to see one of these psychiatrists about whom she had heard so much.

* * *

A new typist and a nodding consultant informed me in the discharge letter that old Mrs. Claypole "had lived for several months on bread and butter and Global Salts." The new treatment for *Weltschmerz*, no doubt?

CHILD GUIDANCE

Be strict in teaching cleanly habits but to see
Evolving an obsessional personality;
Be lax and you may live to curse
Enuresis or worse.

Chastising for each misdemeanour surely bends
The character in sadomasochistic trends;
Never punish and impress
A selfish lawlessness.

Exhibit deep concern and dote unceasingly
To make the child fixated in a high degree;
Deny all love and note oft times
Delinquencies and crimes.

Perhaps the very ancient Chinese wisdom lends
Some help to our debating analytic friends:
Always avoid extremist zest,
The golden mean is best.

Letters to the Editor

QUARANTINE MEASURES IN POLIOMYELITIS

SIR,—Might I be allowed to congratulate the medical officer of health and the general practitioners concerned on the results of their quarantine measures in the outbreak of acute poliomyelitis reported in the article by Dr Goffe and Miss Parfitt in your issue of June 4 Only one further case developed, and the summer outbreak, which we have learnt to fear following the occurrence of later cases in an area, did not occur

I should also like to congratulate Dr Goffe and Miss Parfitt on their confirmation of the high incidence of infection in the contacts of the 4 cases of acute poliomyelitis (8 out of 17 household contacts, and 1 child in the village school attended by 3 of the contacts, were excreting the same type of poliomyelitis virus in their stools) It is on this concentration of virus round the index case that the justification for the inconvenience of quarantine of contacts depends

While welcoming the findings of these laboratory workers however one must question their interpretation of them So far from being satisfied with the success of the quarantine measures, they write Quarantine measures applied in this community did not prevent the spread of infection ' and 'infection was widely disseminated in the community ' Since the disease failed to spread and *no attempt* was made to study individuals who were not either direct or indirect contacts it is difficult to see on what they base these conclusions surely not on the finding on two occasions (January and March) out of four (February and May) of virus of the same type (type I) in town sewage draining other houses than the cases ? The relation between virus in sewage and acute poliomyelitis above ground is at best a very loose one—indeed as they point out, type II virus had been isolated from the same sewage on two occasions in the previous year without accompanying disease above ground—and such findings can hardly be regarded as convincing evidence of widespread dissemination

What really appears to have worried these workers was that their infected contacts continued to excrete virus in their fæces beyond the recommended period of quarantine. 'Quarantine they write, 'seems to be of doubtful value *in practice* if at the end of three weeks three-quarters of the infected members are to be returned to the community still carrying virus ' (my italics) They mean of course, that its value is doubtful *in theory* or more accurately, *in their theory* *In practice* it is of value, and there is a perfectly good theory to explain this—namely that infectivity and fæcal infection ' are not synonymous It is after all only against infectivity that quarantine restrictions are aimed and there is ample epidemiological evidence that, at any rate in countries with adequate disposal of sewage the period of infectivity corresponds not with the known prolonged period of fæcal carriage of the virus (three months is the figure given by the expert committee of the World Health Organisation which Dr Goffe and Miss Parfitt quote) but with the very much shorter period of pharyngeal carriage

Had these workers studied virus in the pharynx instead of virus in the fæces they would have understood why in both practice and theory quarantine need be enforced only for three weeks following contact as recommended by both the Ministry of Health and the World Health Organisation Had they gone further and correlated the findings of virus in the pharynx with the level of antibody in the blood they *might* have shown it a reliable means of distinguishing contacts who because they still carry virus in their pharynx are dangerous to the community from their fellows who, while excreting it in their fæces are past the dangerous stage of pharyngeal carriage

Is it too much to hope that they will study this aspect in the next outbreak which comes to their notice so that we can have the advantages of quarantine and at the same time inconvenience as few contacts as possible for as short a time as possible ?

MARGARET AGERHOLM

COMPLICATIONS OF CHLORPROMAZINE THERAPY

SIR,—In their valuable article in your issue of June 4 Dr Lomas and his colleagues state that epileptic fits occurred in 10 of their 800 patients They do not give the frequency or number of fits but they say that the occurrence of fits is regarded as a contra indication to chlorpromazine Since chlorpromazine has been in use at this hospital epileptic fits have occurred in 3 patients 1 of these patients had had a leucotomy but had never had an epileptic fit before 1 patient had only had one epileptic fit eight years previously while the 3rd had never had an epileptic fit in the ordinary way but had had six seizures during a course of insulin-coma therapy

These patients were investigated electro-encephalographically after the fits. The first 2 patients had normal records. The 3rd showed an unstable alpha rhythm in the resting record. There were no changes on flicker stimulation but overbreathing caused some runs of 5 per second generalised activity and also bilateral sharp wave discharges, especially anteriorly

These 3 patients were then given 50 mg. of chlorpromazine intravenously the E E G again recorded, and the response to flicker and overbreathing observed. There was no change These patients have continued to take chlorpromazine without a recurrence of their fits. We believe that the fits might have been due to the fact that when the patients were placed on chlorpromazine the barbiturate on which they had been previously was withdrawn

At this hospital we have also carried out a series of daily direct eosinophil-counts, and all patients, with one exception, appear to have shown a significant fall after the institution of chlorpromazine therapy instead of the occasional rise observed by Dr Lomas and his colleagues Collateral tests designed to measure possible effects of chlorpromazine therapy on ketosteroid levels and water metabolism have been inconclusive.

I A SAMAD

CHILDREN IN HOSPITAL

SIR —I have read with interest your commentary (May 28) on Dr Mary Capes's World Health Organisation report on this subject.

It seems to be generally accepted that a child should not be admitted to hospital unnecessarily in view of the risk of emotional damage involved With our present-day facilities however it often is essential to admit a child to hospital, but if a method could be devised of taking hospital facilities to the child in his own home it should be possible to nurse at home many children who at the moment would be judged to be requiring hospital care

Thinking along these lines, the idea for a domiciliary pædiatric service has occurred to me involving the following main features

(1) A domiciliary visiting team, which would consist probably of consultant registrar resident and sister It would undertake the care of sick children at home It would visit daily or oftener if necessary and be on call at all times. It would undertake the same investigations, treatment, and research projects as it would if the patients were in hospital instead of their own homes.

(2) A special van or ambulance in which the team would travel It would be furnished with equipment to perform investigations and treatments such as blood-counts X ray examination, blood transfusion, and paracentesis Some procedures such as lumbar puncture could be performed in

it if the home conditions were unsuitable It would also be available at all times and be equipped with radio for easy contact in an emergency

(3) A staff of pædiatric nurses, under the charge of the sister They would care for the children, perhaps working on a shift system A very ill child, or one on special treatment such as intravenous drip therapy, would require twenty four hour attendance, several less ill children would be cared for by one nurse The child's mother would assist the nurse as far as possible, and gradually take over from her as the child recovered

The service, which would be based on the local children's hospital or ward, would be called in by the general practitioner confronted by a case which he would normally send to hospital He would resume responsibility for the case as soon as the child's condition warranted it

This scheme is intended for medical cases, but its use might facilitate the earlier discharge of surgical cases

It is a purely tentative scheme, which is no doubt capable of much modification and improvement Nevertheless, I feel that by its use many children could be spared the potentially traumatising experience of separation from their mothers at a time when they are least able to tolerate it

Edinburgh JANET HAZELL

CANCER RESEARCH

SIR,—It was startling to read Dr Burnet's letter of May 21 and his protest against the present methods of cancer research To abandon experimental methods in favour of bedside observation and to use the money saved to build hospitals would block the sources of all progress and knowledge It is false to maintain that research has " proved absolutely fruitless " The clinical picture of cancer is well known and there is nothing to be added to textbook descriptions But experimental work is of the greatest importance I need refer only to the great many discovered carcinogens (about 700) and their effect

The research of the last fifty years has yielded remarkable results, though I must admit that the practice of therapy is hobbling behind in comparison with the theory We are surely now at a stage where success is written with sympathetic chalk on the blackboard over which the lucky scientist will one day wipe a sponge Patience and assiduity are necessary Experiments on animals cannot be avoided, because every progress in our field comes from the laboratory

Düsseldorf TH OLBERT

HYPERSENSITIVITY ANGIITIS

SIR,—We were most interested to read Dr Rose's comments in your issue of June 18 It seems to us, however, that to attribute a condition such as polyarteritis to drug sensitivity, or to any cause, is not a matter susceptible to proof until sufficient observations have been recorded to be the subject of statistical analysis More frequently, indeed, opinion comes to be a matter of the most reasonable probability in the light of collected experience this being a justification, Sir, for the recording of single cases

In our patient, it seemed more reasonable to us to accept a relationship between the various and at times dramatic manifestations of drug sensitivity, and the simultaneous exacerbations of the polyarteritis which eventually proved fatal, than to postulate that the polyarteritis of whatever ætiology, was progressing quite independently

Satisfactory as Dr Rose's personal experience of cortisone treatment of over 40 cases of polyarteritis (mostly through the Medical Research Council) has been, this has clearly not been the case with our patient, nor with those of other authors quoted by us

MENTAL RETARDATION

SIR,—The second footnote to Dr Alford's articl (June 18) may give rise to confusion The article doe appear to deal also with the lower grades of menta deficiency, as in the remark " when a child is born wh is obviously mentally defective " A child recognise to be mentally defective at birth is unlikely later to be i the " educationally subnormal " category

The present distinction between educationally subnormal and ineducable does, I feel, affect adversely th parents of the ineducable, and serves no useful purpose The statutory notification of the ineducable to the loca health authority labels the children unnecessarily Surely the most humane and logical procedure would b to retain such children in the school system, by makin education authorities responsible for occupation centres Support is given to this suggestion by the recent approva of the Ministries of Health and Education to the application of the term " teacher " to staffs of occupatio centres A circular letter from the National Associatio for Mental Health, dated June 13, 1955, quotes a remar of an officer of the Ministry of Education " it appear to be increasingly recognised that there is no essentia difference between education and training "

Admittedly some of the lowest grades of mentall handicapped children require institutional care, bu admission to hospital should be possible without lega procedure Amendment of the law relating to menta health—now under consideration—should abolish th artificial line of demarcation between educable an ineducable children, with resulting advantage to th mental health of the parents of the latter

DIGITAL ARTERIES IN RAYNAUD'S DISEASE

SIR,—I have read with great interest the article b Mr Lynn and his colleagues (March 5), particularly a its appearance was almost simultaneous with that of paper of my own on the same subject[1] If the term " Raynaud's phenomenon " is restricted to patients i whom (*a*) there is no discernible primary disease an (*b*) there is no evidence of arterial occlusion, at least i the early stages, I have found, in this country, tha " Raynaud's disease " accounts for only a minority o instances of " Raynaud's phenomenon " Among th latter, there is a group of patients with clinical evidenc of structural occlusion of digital arteries and arteriographic features of the kind described by Mr Lynn an his colleagues

I would criticise their suggestion that the term " thrombotic digital artery disease " should be used in these cases This is unjustifiable in the absence of histological evidence that thrombosis is the usual mechanism of the occlusion I had used a similar term until one of my patients died a few months following clinical evidence of digital arterial occlusion the arteries of the hand were dissected and the digital arteries (communis and propria) were found to be occluded not by thrombus but by intimal proliferation Since then I have bee content to say " digital-artery occlusion, cause unknown "

Like Mr Lynn and his colleagues, I have found sympathectomy disappointing in these patients In fact, it sometimes seemed to make the condition worse. However, I do not think that arteriography is essential to distinguish structural from functional occlusion of digital arteries This can readily be done by an arterial occlusion reactive hyperæmia test performed in the manner described by Lewis and Pickering[2] In normal persons and those with functional arterial block, the fingers flush to their tips in less than five seconds after the release of the occluding cuff on the arm In those with blocked

---

1 *Med J Aust* March 26, 1955 p 455
2 Lewis, T , Pickering, G W *Clin Sci* 1933, 1, 327

digital arteries there is a definite delay in flushing of the affected fingers. The findings from this test correlate very well with those of arteriography.

A. J. BARNETT

EFFECT OF HYDERGINE ON UTERINE ACTION

SIR,—The article by Professor Jeffcoate and Mr Wilson in your issue of June 11 raises once again the important question of the ethical justification of using normal healthy patients as experimental material. One appears that in this case 59 patients in perfectly normal labour were given intramuscular injections of 'Hydergine' and another normal group of 5 were given it intravenously. They were already having routine injections of morphine and pethidine and were in no sense in need of further treatment. The hydergine was administered solely for the scientific purpose of determining its effect upon the uterus, and in a few cases of ascertaining if it had the effect of neutralising oxytocin given by intravenous injection.

In [illegible] of the cases "the treatment seemed to cause a considerable increase in the amount of pain," and in another group 6 women whose pain was increased had to be given pethidine intravenously. The conclusions drawn from the tocographic records made in a number of cases were that hydergine can induce hypertonus but that its oxytocic action is not so strong or *dangerous* as that of dihydro-ergotamine ' (my italics).

There can surely be no question but that the giving of the drug involved some risk however slight and the question therefore arises how many of us would permit our own wives to be subjected to this kind of experiment and secondly, were the wives and their husbands fully informed as to the nature of the tests and permission obtained in these cases. I feel that to clear up any possible misunderstanding some explanation on the part of the authors would be welcomed.

Camberley Surrey

M. BEDDOW BAYLY

*** Dr Bayly's letter has been shown to Professor Jeffcoate and Mr Wilson, whose reply follows.—ED. L.

SIR,—We agree that those undertaking 'clinical research' have a duty to avoid experiments which are unnecessary to the treatment of the individual patient and which carry risk of injury or discomfort. It is doubtful where to draw the line and it could be argued that some of the routine tests carried out everywhere today as part of the investigation of many patients are strictly unnecessary or that it is culpable ever to try out a new pattern of obstetric forceps. Sometimes however there is a clear need to weigh carefully the claims of advancing knowledge against the interests of the individual, and the decision to embark on a particular research project can be difficult, and its propriety a matter of opinion. Such issues could be debated at length but they are not strictly relevant to our work with 'Hydergine,' about which there appears to be some misunderstanding in the mind of Dr Bayly.

We were not experimenting in the accepted sense of the word but merely administering a substance which in recent years, has achieved a wide reputation for giving a woman a speedier and more comfortable labour. Thus hydergine and allied compounds are or have been given routinely to parturient women in certain clinics in this and other countries, and even within this last week we and we assume other members of the medical profession have received yet another postal advertisement extolling their virtues and advocating their use. We therefore applied what can be described as an accepted line of treatment designed to help the patient and the only [illegible] was an attempt to control treatment by withholding it from certain women (for which it might be more reasonable to blame us) and by recording uterine action with our external tocograph which is scientifically unsatisfactory but has the merits of depriving the patient of the risks and discomforts which accompany other methods which have a stronger appeal to the experimentalist.

Our finding that hydergine appeared to intensify rather than relieve the pain of labour in certain cases was opposite to what was expected and contrary to the claims of other observers. Moreover our observations that hydergine and dihydro-ergotamine are potentially dangerous arise *as a result* of this and similar clinical studies and were previously unsuspected. In fact, however there is no evidence that any mother or baby in our series suffered harm from their use, and the discovery of their potential dangers under conditions which guaranteed safety may help to avoid their being used harmfully under other conditions.

In short, we gave to a woman in labour a substance which medical opinion assured us was of value to the individual and free from risk. The fact that our experience did not substantiate this opinion is merely an example of an ever recurring situation in which the early exponents of a new method tend to be prejudiced in its favour by enthusiasm whereas subsequent workers uncover disadvantages not previously appreciated.

J. K. WILSON

Liverpool

A BARBITURATE ANTAGONIST

SIR,—I agree with Professor Shaw and Mr McCallum (June 11) that there is some evidence that phenobarbitone is at least partly broken down in the body. My main reason for believing that any such breakdown products do not contribute significantly to blood phenobarbitone levels estimated by ultraviolet spectrophotometry is that I have identified phenobarbitone by paper chromatography in 5-ml. samples of blood taken from patients as long as ten days after ingestion of the drug. On the other hand, I have not been able to demonstrate by this method the presence of spots in any other position than that occupied by phenobarbitone. It is unlikely on theoretical grounds that breakdown products would travel on paper chromatograms at the same rate as the parent substance.

A further point is that the rate of disappearance of phenobarbitone from blood is slower but of the same order as that of barbitone. It is generally agreed that barbitone is stable in the human body.

Professor Shaw and Mr McCallum do not agree that "the worth of new barbiturate antagonists can be evaluated by a measurement of drug levels in the blood." They add that "the only test is the pragmatic one of a lessening of the duration of coma and the mortality rate."

In the light of these statements I have studied with great interest the recent paper by Professor Shaw and his colleagues.[1] The case notes show that ββ methyl ethyl glutarimide (N.P.13) and 2:4 Diamino 5 phenyl thiazole hydrobromide or hydrochloride (D.A.P.T.) do indeed have analeptic activity especially where short-acting barbiturates are concerned. But in 10 cases of prolonged coma (9 of which were due entirely or in part to phenobarbitone) the authors appear to have been unable to restore consciousness without risk of inducing convulsions. In 7 cases for whom the amount of phenobarbitone ingested is recorded my calculations (which assume a body weight of ten stone in each case) lead to the conclusion that only 2 (cases 18 and 21) regained consciousness earlier than might be expected without analeptic therapy—i.e. blood phenobarbitone level above about 5 mg. per 100 ml. During the period of coma these patients are said to have been maintained in the "safe state "—but how safe is a state bordering on convulsions? This is a question which those familiar with the effects of picrotoxin have asked for many years

---

[1] Shulman, A., Shaw, F. H., Cass, N. M., Whyte, H. M. *Brit. med. J.* May 21, 1955, i, 1238.

The specificity of a barbiturate antagonist should be proved in cases of poisoning due to the long acting barbiturates for, in my opinion, prolonged coma in such patients is usually due entirely to the presence in the body of unchanged barbiturate (unless such breakdown *products as may occur are also biologically active*) and not to the effects of shock and anoxia

The London Hospital, E 1 J T Wright

TEACHING DEAF CHILDREN

Sir,—As pointed out by Mrs Ingall in your issue of June 11, there seems still to be a certain amount of confused thought about the stage at which special education of the young deaf child should commence It cannot be sufficiently stressed that early lip reading training and the use of any available hearing should start *as soon as the diagnosis is made* Moreover, this diagnosis must be made at the earliest possible moment after birth, or after the child has suffered from any illness which has produced damage to the hearing mechanisms

On the other hand, the 1944 Education Act should not be regarded as an educational textbook Section 34 of this Act lays down merely that handicapped children may be "ascertained" at the age of two and can be afforded facilities for special education from that age if the local education authority thinks fit Since the diagnosis of congenital deafness can be made in the otherwise normal child in the majority of cases by the age of twelve months, and is often made by their mothers long before this, the work of a number of hospital clinics and local health authorities with these patients is gratifyingly on the increase

The tendency to postpone a decision about the disability arises from the misconception that the necessary training for these young children involves admission to a special residential school This is completely inaccurate, for where the home conditions are suitable the parents can give more help by home training under the guidance of a teacher of the deaf than can be given to the child in a nursery school It is more economical of teaching man power and avoids the psychological consequences to the child due to its removal from the sense of security provided by home and parents

Eye Ear and Throat Hospital,
Murivance, Shrewsbury E N Owen

FOOD IN MENTAL HOSPITALS

Sir,—Having devoted a considerable time to nutritional studies in a mental hospital during the past few years, I greatly welcome Mr Harington Hawes's article of June 11 Most of us will agree with his criticism of present day catering arrangements, and especially the long wait between the early meagre supper and next morning's breakfast

There are several aspects which can be raised in discussing food in mental institutions Our data gained in a hospital with over 2500 beds are being evaluated at present and no ultimate conclusions can be drawn yet It can, however, be said that (at least in the hospital in question) the overall nutritional state of the patients was satisfactory and frank nutritional deficiencies were only rarely found, although some of the patients had been in hospital for several decades Indeed some of the worst acute deficiencies were found in newly admitted patients

Our preliminary publications[1] demonstrated low carotenoid values and low vitamin A and vitamin C reserves among the hospital population, and I therefore would support Mrs Pulvertaft's suggestion (June 18) of spending any additional available funds on fruit, salads, milk, and cheese The detailed results of ou studies will be published shortly

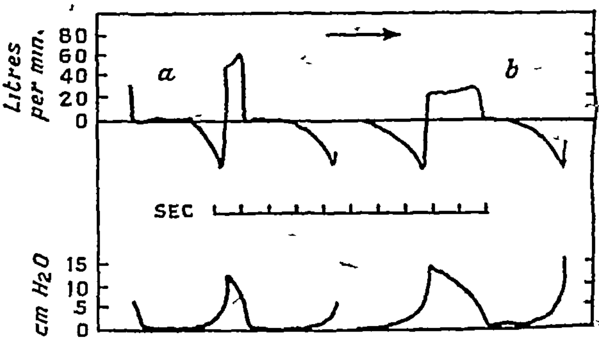
London, W 1 Z A Leitner

ARTIFICIAL RESPIRATION BY INTERMITTENT POSITIVE PRESSURE

Sir,—Dr Spalding's article of May 28 rightly stresse *the way in which the degree of the distension of the lung* within the thorax depends upon the air pressure applie to the air passages, provided that the air passages ar not blocked and that there is no undue rigidity or resis tance of the chest walls

I feel, however, that his conclusion—that prolongatio of inspiration beyond 1 5 sec provides little useful increase in tidal air—may be open to the misinterpretation tha this figure is a physiological constant Surely, it must depend as much upon the machine as upon the patient

If one considers a point 0 1 sec after the start of inspiratio (fig 5*b*) it will be seen that the pressure close to the externa end of the endotracheal tube had already risen to 10 cm. H_2O The cause of this pressure must have been the resistance o the "airway" (endotracheal tube, air passages, &c) to the flow of air, for, so early in inspiration, the elastic restraint o the lungs in thorax must be very small From fig 3*b* we can see that the rate of flow of air must have been 40–60 litre per min. at this instant When such instantaneous rates o flow are available, it is not surprising that a respectable tidal volume can be fed into the lungs in 1 5 sec or even less



Two sample inspirations using a respirator set to change to expiratio at above 13 cm H_2O

Dr Spalding's machine evidently had the very good characteristic of being able to supply 40–60 litres per min. against 10 cm H_2O back pressure, even when set so that its maximum pressure could not exceed 15 cm H_2O Unfortunately, many respirators are not so good and when they cannot provide air flow so freely it is surely no longer true that prolongation of inspiration beyond 1 5 sec provides little useful increase in tidal air

The accompanying figure shows flow diagrams of two sample inspirations using a pressure sensitive respirator set to cut off and change to expiration at about 13 cm H_2O The lower traces are of the pressure near to the external end of the endotracheal tube In flow tracing *a*, air flowed into the lungs at about 60 litres per min at the start of inspiration and continued at about this rate until 0 8 sec later when (from the area of the trace) about 700 ml. tidal volume had been insufflated and the pressure due to distension of the lungs amounted to 13 cm. H_2O, so that inflation ceased In tracing *b, in order to simulate many less satisfactory* respirators, the maximum flow was restricted to about 35 litres per min At the end of 2 sec, air was still flowing in at about 30 litres per min but since (from the area of the trace) some 750 ml had been insufflated, the distension of the lungs had resulted in a pressure of 13 cm H_2O and inspiration ceased In the latter case, useful tidal air was obviously being added at 1 5 sec. and beyond

Even more exaggerated effects can be shown but I wished to work within practical limits There is a respirator on the market which cannot deliver air faster than 15 litres per min.

The pressure curves corresponding to the flow diagrams are very different from any Dr Spalding shows This must have been because the resistance of the “ airway ’ was less in my patient than in Dr Spalding’s Again, if we consider a point 0 1 sec after the beginning of inspiration air was flowing through the airway at 65 litres per min., but the pressure driving it was only 3 cm. H_2O Such possible variation in the airway resistance in healthy people is surely another reason why Dr Spalding s figure must not be misinterpreted as being a physiological constant.

---

[1] Leitner, Z A *Brit J Nutr* 1952, 6 viii Leitner, Z A. Moore T, Sharman I M *Ibid*, p x, *Ibid*, 1954, 13 xi

I agree with Dr Spalding that it is desirable that inspiration should be as short as possible and to this end, the respirator should be able to feed in a lot of air quickly The practical limit to the speed of inflow at the beginning of inspiration will be the resistance of the airway and the highest pressure which is considered permissible at the external end of the endotracheal tube For a given peak or cut off pressure respirators vary a good deal in their ability to deliver big flows against back pressure

Dr Spalding rightly underlines the importance of the short inspiratory phase in maintaining a low mean intrathoracic pressure and thus avoiding embarrassment to the circulation It is worth mentioning that this end can also be served very effectively by applying suction during the expiratory phase

PERIODIC SYNDROME

SIR,—With reference to Dr Reimann’s letter last week on cyclical vomiting his work on recurrent neutropenia is well known With Dr C T de Berardinis he has described[1] the condition and similar cases have been seen in this country[2] Early in my research I thought that I had met with some myself The patients had recurrent pyrexia abdominal pain and neutropenia Some of them had arthritis and splenomegaly However the work of Barrett and Rickards[3] led me to suppose that they may have been suffering from brucellosis despite negative agglutination tests Dalrymple Champneys[4] has pointed out that this condition may last for as long as forty years It is most important in such cases to perform a brucellin skin test, and to determine whether this provokes a rise in titre of agglutination

HUGH R E WALLIS

TREATMENT OF CHRONIC AMŒBIC DYSENTERY

SIR,—I have read the article by Lieut Colonel Inder Singh (March 12) and the subsequent correspondence (March 20 and June 11) with interest, but I have been struck by the complete absence of any mention of clinical findings. It has always struck me that the essential difference between amœbiasis, a disease, and amœbic infestation a harmless parasitism is that in the former there is always a massive invasion of the gut wall, which is easily detectable clinically by a gross thickening and tenderness of the cæcum and colon If this is present whatever the stool findings may be a course of systemic amœbicides must be given which if there is any liver tenderness on percussion should include chloroquine

I wish it were possible to believe as Dr Andrade (June 11) implies that one cannot contract the disease from one s own harmless infestation It seems to me more likely that the parasite after ingestion is forced to feed on the less favourable pabulum of bacteria because of a high host resistance; if however this becomes lowered there is an immediate widespread penetration into the gut tissues by the amœba in whatever form it may be multiplying at the time For this reason I think that if cysts are found without evidence of the disease, they are best killed and a week s course of one of the bisarsenates usually seems adequate for this purpose For those in whom attacks of the disease are common—i e , those with a low natural resistance—it would seem that a prophylactic amœbicide should be possible and I am now trying a combined tablet of bisarsenate with chloroquine, two twice weekly

I believe that as the clinical diagnosis of this disease is comparatively easy too much attention need not be paid to the stool findings the difficulties of which have already attracted a wide literature[5]

Calcutta.

ROGER LANE

HEROIN

SIR,—Following the letter from Mr Southwood in your issue of June 11 deploring the action of the Government regarding heroin, you add an editorial annotation in which you refer, in perhaps a somewhat misleading manner, to the report of the representative meeting of the British Medical Association in the same issue Would it not have given a fairer view of the question to have stated that the meeting passed a resolution protesting against and asking for a reversal of, the ban on the manufacture and use (but not the export) of heroin ?

Moreover the same representative meeting passed a resolution wishing it to be made known that the B M.A had not been consulted or asked for an expression of its views in any way on the question of the abolition of the manufacture and use of heroin

Nor was the question of a ban on heroin referred to the Royal College of Physicians Had it been there is little doubt that a majority of fellows would have given advice quite different from that tendered by the Central Health Services Council which certainly cannot be regarded as representative of those in active medical practice

Incidentally had you Sir read the letter in *The Times* of May 18 from members of the staff of University College Hospital Medical School it would have been obvious that any action taken in this country could have no effect on heroin addiction, in this country or elsewhere

*** An editorial on this subject appears on p 1311—ED L

STERILISATION OF BLANKETS

SIR,—The paper by Dr Blowers and Dr Wallace in your issue of June 18, as evidence of interest in the sterilisation of hospital blankets is very welcome Contrary to the opinion expressed in this paper Fixanol C has not an unpleasant odour does not stain the blankets and it does dissolve in water—perhaps not easily but sufficient to give a dilute solution which is all that is necessary We were the first to recommend the use of Lissapol to remove traces of soap from blankets to be treated and to act as a cleansing agent to replace soap As Dr Blowers and Dr Wallace state, soap antagonises the bactericidal effects of quaternary ammonium compounds we also mentioned this effect in our paper in your columns last year[6]

Epping Essex.

FRANK MARSH

ANTI-HISTAMINES AS HYPNOTICS

SIR,—To depart completely from the basic technique of the trials described in your annotation of May 7 might it not be much more conclusive to carry out tests, for hypnotic action in the subject who *wishes* to be wakeful ? That is, in any normal person (the nearer normal the better) during the day while at work

I suggest that the omission of breakfast and the substitution of the top dose of any anti histamine drug with a reputation for marked soporific side action will leave the investigator in no doubts whatever as to its activity in this direction Placebos could be included in such tests the preoccupation with work mitigating any purely psychogenic response

[5] Lane R, *J trop Med* 1951 54 195
[6] Marsh F Rodway H J *Lancet* 1954 i 125

If it is wished to place the trials on a scientific basis, then experimental subjects could perform standard tasks for evaluation by independent observers, here it might be desirable to add a drug of known hypnotic value, for purposes of qualitative comparison

Port Elizabeth
South Africa
R E HOLMES

BY ANY OTHER NAME

SIR,—I am a philatelist and therefore interested in the details of printing processes In order to elucidate the problems which arise it is often necessary to gaze at some thousands of copies of the same stamp Here I am faced with the same sort of problems (mentioned in your leader last week) that beset the chest radiologist I am looking for minute flaws, sometimes obscured by postmarks He is looking for similar defects sometimes obscured by rib shadows, &c

The great difficulty is to focus both mind and eye on each part of the stamp or film in turn This is very tiring and one tends to overlook the areas in which flaws are less common and to miss them altogether where the design is complex Moreover, the mind looks for the usual type of flaw and is apt to miss the unusual

I am not sure what the remedy should be I think one should have the normal in mind—which will happen after looking at 100 or so films or stamps—and should then strive to focus in turn up one side of a stamp or film, down the middle, and up the other side But I still have much the same error rate as the radiologist

Sevenoaks, Kent
GORDON WARD

SWEETS AND DENTAL CARIES

SIR,—Once again the medical profession is fighting a (? losing) battle against vested interests

Cigarette manufacturers won the fight against prevention of bronchial carcinoma, and now sweet manufacturers are considering how further to increase their enormous sale of sweets, which is already the highest per head in the world

One only has to live near a sweet shop, and watch children coming and going there all hours of the day, to realise how hopeless the fight is for prevention of dental caries

Unless there is an active press campaign, assisted by explanatory talks by dental officers in schools and clinics, and medical practitioners in surgeries, homes, and elsewhere, pointing out the danger of sucking lollipops, toffees, and suchlike, the number of dental casualties will go up and up

What about a high purchase tax on "dangerous" sweets ?

Nottingham
G FIELDING

DANGEROUS COTS

SIR,—I have a certain amount of sympathy with the views of the cot manufacturers which you criticise in your annotation of June 18 Those who work in children's hospitals will agree with me when I say that only eternal vigilance can prevent accidents If not watched children will pour soup over themselves, eat their coloured pencils, push buttons up their nose, and undo their bandages I know of one fever hospital where the superintendent gave instructions that cot sides must not be put up because when children climb over them (and they do !) they have so much further to fall At another, no restrainers are allowed because some years ago a child was killed by getting entangled in one Narrowing the distance between bars may prevent one type of accident, but accidents are not caused so much by faulty equipment as by the restlessness of children exploring their world with great determination and little sense They need conscientious nurses to watch them whatever type of bed they are in

There is a further point I should like to make Our toddlers' ward at present houses 20 children between three and five, none of whom could be squeezed through the bars of his cot in the manner you describe and most of whom wear, in addition, plaster jackets or various types of splint Yet, I am told, the Ministry circular leaves our administrative staff no choice but to change our present cots for new ones at the expense of several hundred pounds To issue a circular calling attention to the danger of one type of child in one type of cot is one thing, to issue instructions altering every cot in every hospital in the country quite another

King Edward VII
Orthopædic Hospital
Sheffield 6
E G HERZOG,
Surgeon Superintendent

SIR,—I suggest that if the bars were placed horizontally the accidents could not occur

London, W 1

*** But would the child stay in the cot ?—ED.L

Obituary

DONALD BREADALBANE BLACKLOCK

C M G, M D Edin, D P H, D T M

FROM 1929 until he retired in 1945, Dr Blacklock filled with distinction professorial chairs at the Liverpool School of Tropical Medicine But he was never content to direct operations on the tropical front, and he continued, on arduous tours to unhealthy spots, his service for those who work in tropical climates

He was born in 1879 at Oban, the son of the Rev John Blacklock From Fettes College he went to the University of Edinburgh, where he played forward for the Edinburgh Wanderers and cricket for the university After he qualified in 1902 he practised for a few years in South Africa, but on his first leave home he met Warrington Yorke, then a research assistant at the Liverpool School of Tropical Medicine's laboratory at Runcorn From this chance meeting there grew a close friendship and scientific partnership, for Blacklock was so fascinated by the work he saw at Runcorn that he threw up his promising South African practice to join the staff of the school In 1907 he took the D P H, in 1909 the M D, and in 1911 the D T M The same year he was appointed research assistant at Runcorn, and he continued to work there until 1914, when he was appointed director of the laboratory and later lecturer in parasitology to the school During these years he produced some twenty papers on trypanosomiasis, most of them in his own name but some in joint authorship with Warrington Yorke One of these papers recorded the important discovery that *Trypanosoma cruzi* could develop to the infective stage in the bed-bug But most of his published work dealt with the morphology of trypanosomes and, particularly, with the discovery of posterior nuclear forms of *T rhodesiense*

In 1914 Blacklock and Warrington Yorke, with the school's 32nd expedition, visited West Africa to arrange for the site of the Sir Alfred Lewis Jones Research Laboratory While in Sierra Leone they studied the breeding-places of *Glossina palpalis* and the species of trypanosomes transmitted by the fly to man and his domestic stock By the time the expedition returned to England war with Germany had broken out, and Blacklock joined the R A M C, to serve in the Dardanelles and France until 1916, when he returned to look after tropical cases at the school, which had been converted into a hospital While he was stationed at home he went on with his research and he collaborated with Stephens, Yorke, and other colleagues in papers on the treatment of malaria These papers, though now obsolete, were at the time of their publication, highly important, for they showed the Army authorities how best to control this disease which so greatly interfered with operations in the field With Warrington Yorke he also studied the periodicity of the microfilaria of *Wuchereria bancrofti*

In 1921, when the Sir Alfred Lewis Jones Research Laboratory was opened by the Liverpool School at Freetown, the University of Liverpool appointed Blacklock director of the laboratory and professor of tropical diseases of Africa During the next eight years, while he established the laboratory on a firm footing he covered the diseases of Sierra Leone on behalf of the government, and directed important research, much of which was achieved only by travelling up country under primitive and trying conditions

His investigation of an outbreak of beri beri in the Freetown jail proved the cause to be the faulty preparation of the rice a discovery which eliminated this long-standing cause of sickness in the prisons During a tour in the northern province of Sierra Leone he observed that in this area a high proportion of cases of goitre were associated with heavy fæcal contamination of the drinking-water In entomology his main interest was the breeding places of the local anophelines and as a result of his investigations anti malarial measures in Freetown and its environs were put on a more scientific basis He also collaborated with his wife Dr Mary Blacklock, in a comprehensive study of the tumbu fly In the course of this investigation he observed evidence of resistance developed by the host against this parasite and with Prof R M Gordon he published papers on this aspect of metazoan immunity His contributions to protozoology included his studies on malaria in the chimpanzee, and again with Professor Gordon on placental malaria. In helminthology Blacklock added much to our knowledge of West African schistosomiasis, and completed, in 1927, the proof that *Onchocerca volvulus* was transmitted to man by *Simulium damnosum* —a pioneer investigation which, for the first time allowed methods of control to be applied to a disease which has been a widespread cause of blindness both in West Africa and in Central America. He was also interested in that strange disease blackwater fever, and he showed that the transfer of blood from the patient to a normal person did not reproduce the infection. Those who knew Blacklock will correctly surmise that this somewhat risky experiment was performed on himself and a colleague recalls appreciatively that he had the discrimination to choose a bishop as his donor

In 1920 he returned to Liverpool to succeed Warrington Yorke in the Walter Myers chair of parasitology, which he held until 1934 when he was appointed to the newly established chair of tropical hygiene But though this chair was now in England, much of his work still lay abroad. In 1935 with a Leverhulme fellowship he visited China, Malaya, Burma India and Ceylon to study the techniques of rural hygiene used in the tropics, while his wife, who held a similar fellowship, made a special study of the health of the women and children Housing in relation to tropical disease was another subject which interested him and he was a member of the Colonial Housing Research Group

During the late war, Freetown was a great convoy centre for war-time shipping and it was vitally essential that this base should be in constant use. Unfortunately the mosquito proved an even more formidable foe than the enemy the crews and the troops on board the ships at anchor in the harbour, as well as the men stationed on shore, were exposed to the bites of mosquitoes and became infected with malaria to an extent which threatened to disorganise the whole convoy system. In this crisis the authorities approached the Liverpool School of Tropical Medicine and Blacklock, now nearly 65 with the rank of surgeon captain R N V R sailed again to the discomforts of West Africa. The success of his work there was soon shown by the fall in the sickness rate which followed the adoption of his recommendations and in 1912 he was appointed C.M.G Besides this well earned honour he also enjoyed the rare distinction of having served his country with the rank of captain in the Army in one war, and captain in the Navy in the next. In 1914 at the request of the Government he again visited West Africa

Blacklock s clear and incisive mind made him an excellent lecturer and the many editions of his *Guide to Human Parasitology* written with T Southwell, bear witness to his powers as a teacher In 1945 he retired from his chair after serving the Liverpool School for thirty four years, and retired to Cornwall He died on June 10 at his home at Mawnan

R. M G writes: Blacklock s acknowledged position as a leader in tropical medicine was not the result of personal ambition for he was the most modest and least self-seeking of men; rather was he carried to the front of scientific research on the tide of his own discoveries and in his advance he brought with him many younger and less experienced colleagues There are today a host of workers in tropical medicine who owe their positions to the early training they received from him, for he had the power not only of imparting knowledge but of inspiring enthusiasm and turning dull routine into a fascinating preliminary struggle with a worth while problem

' Blacklock travelled widely and studied tropical medicine in every part of the world but his name will always be associated most closely with his work in West Africa, particularly in Sierra Leone, a colony from which he did more than any other man to remove the stigma of the white man s grave It was in Sierra Leone that he carried out the manifold researches in entomology and parasitology which are recorded in his published works It was in Sierra Leone that he made the discovery which ranks high in the annals of tropical medicine, of the transmission of *Onchocerca volvulus* by *Simulium damnosum* and it was to Sierra Leone that he returned during the late war to solve the problem of malaria control in Freetown.

Despite his reserved manner, he was universally popular and he will be mourned by many friends in many parts of the world and in every rank of life The reason for this unsought popularity was not far to seek he was a fine man in every sense of the word fine in body, fine in intellect, and possessed of a wonderful power of ignoring the worst and perceiving the best in his fellow man

Professor Blacklock married in 1922 Mary Georgina, daughter of George Matthew Thompson M.D., of co Derry who survives him As his student and later as his colleague in West Africa, she shared in much of his research.

REDCLIFFE NATHAN SALAMAN

M.A M D Camb., F R.S. J.P

Ill health forced Redcliffe Salaman to give up medicine four years after he qualified, but it remained within the range of his flexible scientific interests As director of the Potato Virus Research Station of the University of Cambridge he made important contributions to our knowledge of virus diseases and he continued to urge the need for closer understanding between the pathologist and the plant breeder

(Walter Stoneman

He was born in 1874, one of the twelve children of Myer Salaman a City merchant. He was educated at St. Paul s School and at Trinity Hall Cambridge, where he studied under Michael Foster Gaskell and Macalister After taking a first in the natural sciences tripos he entered the London Hospital He began to do research even before he qualified in 1900 and after holding a house-appointment under Henry Head he continued his postgraduate studies and research at Würzburg and Berlin On his return he was appointed director of the pathological institute at the London Hospital and pathologist to the Zoological Gardens. But in 1904 he developed pulmonary tuberculosis After eighteen months in Switzerland he returned to England restored to health, but decided to spend his life in the country He accordingly settled at Barley in Hertfordshire where he began his genetic and agricultural researches His special interest was the potato plant, and in 1920 he published the results of many years private investigation in his book *Potato Varieties* The same year he persuaded the late Sir Daniel Hall and the Ministry of Agriculture to found a research station at Cambridge to investigate the virus diseases of the potato He became director of this institute and soon afterwards with R H Le Pelley published a description of the virus latent in all potato plants of the King Edward variety which he named the Paracrinkle virus. "This discovery," writes K. M. S., "gave great impetus to the study of latency in plant viruses, and is still one of the strongest pieces of circumstantial evidence for the endogenous origin of some plant viruses. By means of careful testing and selection he also built up a nucleus stock of virus-free seed potatoes which were grown under insect-proof conditions in the Cambridge glass-houses. From this stock small quantities of each variety were multiplied up each year out of doors under conditions of strict isolation from all other potato plants. Much of this work was done on a small island off the west coast of Scotland where there were no other potatoes being grown. These nucleus potato stocks are still in existence and their propagation and care are now under the direction of the National Institute of Agricultural Botany at Cambridge. This idea of raising virus-free stocks of potatoes with a view to improving the yield and quality of the crop generally has now been copied in many other countries. Salaman's interest, however, was more in the potato plant than in viruses, and he spent much time in breeding new potato seedlings for resistance to potato blight, *Phytophthora infestans*."

In 1935 he was elected F.R.S. In 1939 he retired from his appointment to spend the next years writing *The History and Social Influence of the Potato* (1949) in which he traced the history of the plant in relation to social and economic conditions.

A man who was thus ready to point out the wider implications of the virus diseases of plants could not fail to have many interests outside his own research, and he had won respect on the magistrates' bench as well as at the laboratory bench. He became a J.P. for Hertfordshire in 1901, and for twenty-three years he was chairman of the bench.

He also gave much devoted and discerning service to the Jewish community, of which perhaps the most important was his chairmanship of the Jewish Committee for Relief Abroad which was founded in 1943. Of this personal side of his life, S. W. writes: "I first met Redcliffe Salaman some 20 years ago. He was an unusually good-looking man, an aristocrat to the finger-tips, quite uninhibited, always saying exactly what he thought without care about the consequences. I never knew him as a scientist and often wondered how a man of such obviously high intelligence and delicate sensibility could have given up the study of man to devote himself to the potato; but he was very good at potatoes. Our common interest at the time was the plight of the scientists, scholars, and doctors who were being driven out of Germany by the Nazi persecution. Salaman devoted every ounce of his energy to this cause. He took great pains to get to know the displaced workers well and used all his influence to find new opportunities for them at home and overseas. He was a pretty good judge of real ability. I remember him saying of one young and relatively unknown biochemist that he was an obvious future Nobel prize-winner; and so he proved to be, and much else besides. What stirred Salaman to action was not only his abiding sense of loyalty to his fellow Jews, who constituted the majority of the victims, but the feeling that the Nazis' behaviour was an affront to all the standards of decency and humanity for which he stood. His other constant love was the Hebrew University of Jerusalem. Though no man was more proud than he of his alma mater, Cambridge, or more touched by the honours it gave him, yet he always referred to the Hebrew University as 'my' university. He had an unlimited faith in the service it would one day render to the Jewish people, the Middle East countries, and all mankind. He put all his wisdom, integrity, and practical experience at the disposal of its board of governors and did much to steer the university safely through its early critical years. He kept in constant touch with all its problems, and until his last illness was willing to see anyone or go anywhere on its behalf if he was told that he could help. Salaman was not a man with whom you could easily become intimate; he was probably more emotional at heart than he was willing to let others know. But he was greatly touched by the honorary fellowships which both his old college and the Hebrew University bestowed upon him during his illness, for he recognised them as tokens that his devotion over many years was fully recognised and appreciated."

Dr. Salaman was twice married. His first wife, Nina, daughter of Arthur Davis, who died in 1925, is still remembered for her translations of Hebrew poetry. They had six children, of whom two sons are doctors. Dr. Salaman is survived by his second wife, Gertrude, née Lowy. He died on June 12 at his home at Barley.

CHARLES ERIC RHODES

M.B. Lond.

Surgeon Lieutenant Rhodes lost his life in H.M. Submarine *Sidon* when she sank after an explosion in Portland Harbour early on June 16. He was medical officer of H.M.S. *Maidstone*, the depot ship alongside which the *Sidon* was lying, and he boarded the submarine with the first rescue party. In difficult circumstances he got some of the wounded to safety. Shortly before the *Sidon* sank he went back to help the others, and he was not seen again.

He was born in Lancashire in 1928, the son of Mr. and Mrs. E. C. C. Rhodes of Bramhall, Cheshire, and was educated at Cheadle Hulme School and Wrekin College. He entered the London Hospital Medical College in 1946, and he qualified in 1952. He was house-physician at the London and house-surgeon at Harold Wood Hospital before he joined the Royal Naval Volunteer Reserve.

J. R. E. writes: "Few men during their years at the London have been more widely known, or more liked and respected. It was impossible not to like someone so obviously happy, enthusiastic about so many things, active in so many ways, and so completely unselfish. He was respected because with all his cheerfulness he was quiet and unassuming, courteous and kind, with sound and fair judgment. He inevitably gave more to the community than he took from it, and his influence was widely felt and good. It was typical of him that at a time when the hospital rugby XV was suffering from a clash of personalities he solved the problem by efficient and tactful service as non-playing secretary. To do so he gave up his own pleasure in a game which he greatly enjoyed, though his poor sight prevented him from being a first-class player.

"In his favourite sport, however, he achieved eminence. Not only United Hospitals, but the Royal Ocean Racing Club and sailing clubs in many parts of the country knew Eric as an experienced helmsman and a delightful companion. Qualification and house-appointments brought a halt to sailing, but his love of the sea made him determined to fulfil his National Service with the Navy. He was within a few weeks of completing it when he gave his life in an act which by its courage, unselfishness, and efficiency was characteristic. The tragedy of the unfulfilled promise, of the loss to medicine, of one who possessed complete integrity and the ability to lead by personal example, is only tempered by the knowledge that he achieved much, and in his end achieved greatness."

He leaves a widow and a daughter born a few weeks ago.

DR. R. A. LYSTER

J. B. G. S. writes: "In your obituary there is no mention of Dr. Lyster's appointment as lecturer in forensic medicine and public health at St. Bartholomew's Hospital. He was a first-class lecturer and made his lectures extremely fascinating and clear. He prepared most useful synopses which students could retain and which contained all the salient points at issue. He was able to illustrate his teaching from vast experience and was evidently a diligent reader of the Press. A frequent remark of his was 'I have a cutting here,' in order to reinforce the point he wished to make. He had a pleasing sense of humour and he told his audience that he did not wish to turn them into 'a set of amateur sleuths'. He made plain the various 'grave risks' the practitioner was likely to encounter in his daily work. He had a dignified bearing, he delivered his lectures with an articulation that will always be recalled by those who heard them. One felt the room listening to statements that had an ex-cathedra authority about them. Although he was not an old Bart's man by training, he was one of many distinguished teachers of which Bart's has always been the proud possessor."

Notes and News

OBSTETRIC MEDICINE RESEARCH UNIT AT ABERDEEN

An obstetric research team has been working under the direction of Prof. Dugald Baird in Aberdeen during the past seven years. To further this work the Medical Research Council has agreed with the University of Aberdeen and the North Eastern Regional Hospital Board Scotland, to form a unit for research in obstetric medicine under the honorary direction of Professor Baird

The Scottish Hospitals Endowment Research Trust has promised a substantial grant to the university for the construction of a building adjoining the Aberdeen Maternity Hospital to house the unit The administration of this building will be arranged jointly by the University and the Aberdeen Special Hospitals Board of Management The building will provide laboratory facilities and beds for patients requiring special investigation whose treatment can thus proceed without interruption.

The unit will continue long term research into problems of maternity using a combination of epidemiological, clinical, and laboratory methods of investigation The term "obstetric medicine" in its title recognises the fact that general health problems, of the type which are the concern of the research physician have become as important as the surgical aspects of obstetrics.

EYE INJURIES IN BOXERS

At a meeting of the honorary medical officers of the London Amateur Boxing Association on May 24 under the chairmanship of Dr J Sharp Grant Eye Injuries were discussed by Mr A. Rugg-Gunn.

Mr. Rugg-Gunn expressed the opinion that no-one suffering from any form of epilepsy should be allowed to box and recalled that patients with squint associated with amblyopia often had an electro-encephalographic tracing similar to that of epilepsy The eye he said was slung well behind the orbital rim and rested behind on a fatty cushion, the most vulnerable part being its temporal aspect, especially in adduction. The orbital rims of hard compact bone were seldom fractured but fractures in the neighbourhood of the inner canthus—e.g., the nasal bone and the naso-maxillary process—were not uncommon The commonest eye injury in boxing was "a black eye" which was rarely serious unless associated with splitting of the upper eyelid or a wound in the neighbourhood of the canaliculi Corneal and conjunctival abrasions might occur with lid injuries Subconjunctival hæmorrhages might arise from orbital hæmorrhages as well as from rupture of conjunctival vessels. A direct blow might rupture the pupillary sphincter muscle and produce hyphæma and subconjunctival hæmorrhages Rupture of the sphincter may cause permanent mydriasis and should be treated immediately with pilocarpine or eserine drops. Transient paralyses of the extra-ocular muscles causing diplopia sometimes followed hæmorrhage into the muscle substance As a rule however paralyses of these muscles were secondary to head injuries and were serious Naturally accuracy of hitting and timing of blows were grossly disturbed. A direct blow on the eye in the eyes-front position might cause serious internal injuries The elastic cornea was dented and waves of force were transmitted backwards through the media displacing momentarily the iris and lens, affecting all diameters of the eyeball, but impinging with maximum force at the posterior pole or macula. Rupture of the choroid possibly multiple and rupture of the retina (less common) might be produced These stress effects constituted so-called concussion firstly temporary vasoconstriction in the macular area, giving rise to ischæmia, and secondly, owing to the anoxia release of histamine-like substances which produced local vasodilatation œdema, and hæmorrhages. Detachment of the retina was relatively common in professional boxers and was often bilateral. Usually its onset was delayed When the onset was immediately after a blow this had probably coincided with temporary obstruction of the venous outflow from the choroid—e.g., through holding the breath—so that the overlying retina was temporarily stretched at the moment of impact Myopes were more vulnerable than others Hæmorrhage into the vitreous disorganising this locally might produce a strand-like opacity which was sometimes anchored at one end to the retinal surface Sudden movements of the eye might pull on the retina at the point of attachment and cause a tear and retinal detachment and this might happen months later Blindness in boxers was usually due to retinal detachment

OLD PEOPLE IN WELFARE HOMES

At the conference of the Association of Hospital and Welfare Administrators on May 25[1] Mr C R Pennell the association's president expressed grave concern that aged and infirm patients were being accommodated in welfare homes and looked after by staff who were not trained nurses. At one large welfare home he had visited some 70 of the people needed nursing care They could not go to an adjoining hospital because there was no room, and Mr Pennell added the local authority could not or would not employ nurses There had been some 40 doctors at this establishment during the first three months of this year But Mr Pennell acknowledged that many local authorities had made vast improvements in their accommodation for old people In fact he said there are cases where lavish might be the correct word to use and sometimes some of the old people may feel a little uncomfortable at being made too *comfortable*

MEDICAL RECORDS

At an exhibition held in London last month by the Association of Medical Records Officers various hospitals had their own stands Charing Cross Hospital gave a helpful exposition of checks and controls over the movements of case notes and also showed how the cards forming the waiting list are afterwards used as admission cards and finally as an index to the files, thus reducing repetitive clerical work. Among the Southend-on-Sea Hospital practices which were illustrated was pre registration of new outpatients, whose time at the clinic is saved by sending them a form to complete at leisure in advance and return by post The numerous other hospital and commercial exhibits included such subjects as storage outpatient appointments medical correspondence and relations between patients and staff A special stand indicated the scope of the educational work undertaken by the Association of Medical Records Officers, including the holding of examinations on a wide syllabus and publication of a quarterly *Medical Record*

As a visual means of presenting a variety of hospital techniques for the consideration of others facing similar problems in their own hospitals and clinics, the exhibition proved a useful innovation

PRESSURE PADS FOR ULCERATED LEGS

The rubber pads ordinarily employed for applying additional local pressure in the compression treatment of ulcerated legs have disadvantages which discourage their general use First, sponge rubber as usually obtainable is tough and springy and can produce a deep dent in the leg Secondly the pads have to be individually cut to size and carefully skived—the latter a tedious affair and inconvenient in a large and busy clinic

Dr Stanley Rivlin of the London Varicose Clinic points out that in practice such pressure is required chiefly in the later stages of healing—when the ulcer has contracted to the size of a half-crown and has either bumpy edges or raised central granulation tissue—and for this reason a pad of standard size will be found appropriate in most cases. To Dr Rivlin's specification the medical division of the Scholl Manufacturing Company have evolved moulded latex foam pad 8 cm. square of "unbelievable lightness, texture and porosity" which he has found admirably suited to the purpose

---

[1] *Manchester Guardian* May 26 1955

Their light weight, he says, ensures soft though firm pressure, while the permeable cellular structure allows healing without maceration

---

University of Sheffield

The council has made the following appointments

Full time—Dr P Anderson and Dr N E Shaw demonstrators in anatomy, Dr K D Neame and Dr F A Jenner, assistant lecturers in physiology, Dr W D Smith, research assistant in medicine

Part time—Dr D A J Tyrrell hon lecturer in medicine, Dr J D S Hammond tutor in medicine for dental students

Royal Medical Benevolent Fund

The annual general meeting of the Fund is to be held on Thursday, July 28, at 5 P M, at 11, Chandos Street, London W 1, with Lord Webb Johnson, the president, in the chair

R A F Appointment

Air Commodore F E Lipscomb has been appointed principal medical officer, Royal Air Force, Home Command, with the acting rank of air vice marshal as from July 1

American Award

A James Picker Foundation grant has been awarded to Dr H A Sissons, morbid anatomist at the Institute of Orthopædics of the University of London, for microradiographic studies of bone structure

Oliver Memorial Fund

The committee of this fund again offer an award of £50 to a British subject for original work or services in connection with blood transfusion Applications should be sent before Aug 31 to the hon treasurer, Mr F W Mills, c/o National Provincial Bank Ltd, Holborn Circus, London, E C 1

National Fund for Poliomyelitis Research

This fund has given £1100 for the purchase of apparatus by the division of human physiology of the National Institute for Medical Research The apparatus will be used at the National Hospital, Queen Square, London, in investigations into cardiorespiratory function in bulbar paralysis conducted by Dr L G C Pugh

The Bone and Tooth Society

This society is holding a public meeting in association with the Ciba Foundation, at 1, Wimpole Street, London, W 1, at 3 P M on Friday, July 15, when some of the proceedings of the Foundation's symposium on *Bone Structure and Metabolism* will be discussed The following members of the symposium will speak Prof A Engstrom (Stockholm), Dr John E Howard (Baltimore), Prof G Fanconi (Zürich), Prof W D Armstrong (Minnesota), and Dr H Lisco (Chicago) Prof R A McCance, F R S, will preside

Prizes for Clinical Research

The following have been awarded prizes in the South West Metropolitan Regional Hospital Board's competition for 1954

Consultants and S.H M O.s—Mr H A. Kidd, St Helier Hospital Dr J F Wallace and Dr Ruth Pillman Aldingbourne Sanatorium Dr D H Bennett Netherne Hospital, Dr J Lomas, Springfield Hospital Dr M M Glatt, Warlingham Park Hospital

Senior registrars registrars and J.H M O.s—Dr E W Ball, South Hants Hospital, Dr J K McKechnie King George V Hospital for Diseases of the Chest, Dr J A Edwards, Knowle and Old Manor Hospitals Mr D A Macfarlane St James' Hospital Balham

Senior house-officers and house-officers—Dr J Kohari, Lambeth Hospital

A similar competition is being held this year and particulars will be sent to group medical committees in the region

Lady Tata Trust

The trustees of this fund announce that they have made the following awards for research on leukæmia and allied diseases, in the year beginning next October

Grants for research expenses—Dr Jorgen Kieler, Copenhagen, Dr Jo Nordmann Paris, Dr Arunachala Sreenivasan Bombay

Scholarships—Dr Flemming Kissmeyer Nielsen and Dr Niels Aksel Stenderup Aarhus Denmark, Dr Jorgen Ringsted and Dr Jorgen Rygaard Copenhagen, Prof H G Teir and Dr C G V Wasastjerna Helsinki

Scholarship and grant for research expenses—Dr Maxime Seligmann Paris

Personal grant—Mr Stanislaw Joseph, Oxford

In addition, a block grant has been made to the Social Medicine Unit, University of Oxford (director, Dr Alice Stewart), for the cost of a pilot inquiry into possible environmental factors in the ætiology of leukæmia in man

Diary of the Week

JUNE 26 TO JULY 2

Monday, 27th

Postgraduate Medical School of London, Ducane Road, W 1
4 P.M Dr R Bing (Alabama) Metabolism of the Heart.

Tuesday, 28th

Institute of Dermatology, St John's Hospital, Lisle Stree W C 2
5 30 P M Dr P D Samman Follicular Keratotic Disorders

Wednesday, 29th

Royal Society of Medicine, 1 Wimpole Street London W 1
4 30 P M *Physical Medicine* Dr Philippe Bauwens Dr W Levitt, Dr Robert Forbes Medicolegal Problems and t Department of Physical Medicine
Institute of Dermatology
5 30 P M Dr Henry Haber Dyskeratoses

Thursday, 30th

Postgraduate Medical School of London
4 P M Dr J F Goodwin Mitral Valve Disease
Royal Society of Medicine
2 30 P M. *Urology* Mr J Cosbie Ross Mr N O K Gibbo Mr David Band Dr A G Hardy Paraplegic Bladder
British Association of Urological Surgeons
9 30 A.M (Royal College of Surgeons of England, Lincoln's In Fields W C 2) Opening of annual meeting
Renal Association
4 30 P.M (41 Portland Place, London W 1) Dr Alexander Le (Boston), Dr Oliver Wrong Volume Control of the Bod Fluids

Friday, 1st

Postgraduate Medical School of London
2 P.M Prof H A Magnus Reticulosarcoma of Bone
4 P M Dr W W Brigden Rheumatic Carditis
Institute of Laryngology and Otology, 330, Gray's Inn Roa W C 1
3 30 P M Mr Wallace Black Congenital Deafness

Appointments

Barclay, David, M B Aberd, D.P H deputy M O H, Aberdeen
Davies, Dewi, M D Lond, M R.C P physician superintenden Ransom Sanatorium Rainworth, Notts, consultant physicia Mansfield chest clinic
Gilliatt, R W, D M Oxfd, M R C P asst physician, Nation Hospital, Queen Square, London
Halliwell Jean M., M B Manc, D OBST, D C H school M Stockport
MacLeod, M. C, M B Glasg, D P H. senior M O and school M Dorset
Manning, Angela, M R C.S asst M O and school M O, Warringto
Patterson Janet B, M B Aberd school M O and asst M O.H Middlesbrough
Rose Clement M D Lond D P M. whole time consultant psych atrist Mapperley Hospital, Nottingham.
Short, Richard, L R C P E D P H area executive M O Nort nos 1 and 2 areas, and M.O H, urban districts of Alnwick an Amble rural districts of Alnwick, Glendale, Rothbury an Norham and Islandshires Northumberland
Swinney, W D M B Aberd, D P.H divisional M O H, Surre (Merton and Morden part of North Eastern Division), M O H Merton and Morden U D C
Watters N M M B Glasg whole time asst ophthalmologis Rotherham Mexborough, and Worksop areas, Sheffield R H B

South Western Regional Hospital Board

Bradfield A M M B N Z registrar in psychiatry, Brist mental hospitals
Edwards, E M. M B Lond, M R C O G, D OBST temporar senior registrar in obstetrics and gynæcology, Bristol clinic area
Hargadon, E J, M B Wales surgical registrar, Cossham Frenchay hospital group Bristol
Roberts, A. G M B B.SC Wales registrar in psychiatry, Moorhaven Hospital, Ivybridge, South Devon
Theobalds, J R. M R C.S medical registrar, Cheltenham General, Eye, and Children's Hospital
Wells A. M, M B Brist D OBST, D C H medical registrar Southmead Hospital, Bristol

Leeds Regional Hospital Board

Calderwood R. W L F R C S asst orthopædic surgeo (S H M O) Pontefract and Castleford group
Hird G F, F R C.S asst orthopædic surgeon (S.H.M.O) Huddersfield group
McCrea P C, M B Belf asst pathologist (S H.M O), Harrogate and Ripon group
March H F, M B Durh, M R.C P, D.M R.D consultant radiologist, York (A) and Tadcaster, and Scarborough, Malton, and Whitby groups
Mather Ida M.B Leeds, D P M asst psychiatrist (S.H M O), Stanley Royd Hospital, Wakefield

Appointed Factory Doctors

Houghton, H J M B Wales Llandrindod Wells Radnorshire.
Lewis, M. P, B.M Oxfd, D OBST Oundle, Northants
